## Abstract

In the European fusion programme, safety and environmental issues are of great importance in the continuing development of power plants. In support of this programme, a sound, complete and reliable neutron-induced cross section data library is required. The European Activation File (EAF) project has been an ongoing process performed through European and world-wide co-operation that has led to the creation of succeeding EAF versions. The latest release, EAF-2010, includes cross section data for deuteron- and proton-induced reactions. As with EAF-2005 and -2007 all cross sections have an upper energy limit of 60 MeV. EAF-2010 has benefited from the generation and maintenance of comprehensive activation files and the development of the processing code SAFEPAQ-II. Cross section validation exercises against both experimental data, systematics and integral data, which were started in 1995, enable a comprehensive and multi-faceted assessment of the data. SAFEPAQ-II is used to apply a series of modifications to the original source data. A very important set of modifications concerns renormalisation and branching using experimental or systematic data. These are challenging tasks when the source contains non-threshold reactions with an energy dependent branching ratio. Although the various EAF libraries are certainly the most-validated activation-transmutation libraries in the world, currently less than 3% of all the reactions can be compared with experimental information, and sometimes then only for very limited, and not always application relevant, energy ranges.

As with EAF-2001, -2003, -2005 and -2007, results of integral experiments have been used to correct, adjust and validate data. This can be done using SAFEPAQ-II by inputting the measured effective cross sections. Validation and verification using integral data has been performed by means of direct comparison with measurements of various materials under fusion-relevant neutron spectra. Irradiations have been carried out at ENEA FNG, FZK Isochron-cyclotron, Serгиеv Posad SNEG-13, TUD, Řež and JAERI FNS and integral C/E comparisons made (C/E is the ratio of the library to the experimental value). In addition available data from the literature have been collected and used. The results of these benchmarking exercises have indicated, in conjunction with differential data, where modifications to the data can be applied.

The EAF-2010 library contains 66,256 excitation functions involving 816 different targets from  $^1\text{H}$  to  $^{257}\text{Fm}$ , atomic numbers 1 to 100, in the energy range  $10^{-5}$  eV to 60 MeV. The 3,660,206 lines that make up the point-wise file are then processed into numerous group-wise files with different micro-flux weighting spectra to meet various user needs. Uniquely, an uncertainty file is also provided that quantifies the degree of confidence placed on the data for each reaction channel.

## Introduction

The European Activation File (EAF) is the collection of nuclear data that is required to carry out inventory calculations of materials that have been activated following exposure to neutrons or charged particles. Along with the inventory code FISPACT [1], EAF comprises the European Activation System (EASY) which has been developed for fusion activation studies.

One of the components of EAF is the collection of neutron-induced cross section data. The present report documents this cross section library, detailing how the library has been developed over a twenty-four year period, describing the methodology employed for its production and testing and providing an index of all the reactions. The present report forms part of the documentation for EASY, other reports cover the FISPACT code [1], SAFEPQA-II [2] and other components of EAF [3,4,5,6].

The current release of the European Activation File, EAF-2010, contains cross section data of neutron-induced reactions for energies between  $10^{-5}$  eV and 60 MeV. This report covers all the reactions. The library contains data for targets up to and including fermium ( $Z=100$ ). A new version of the library has been produced by the SAFEPQA-II tool, which uses data from various sources and applies a series of modifications. The choice of data sources and the basis of the modifications use the knowledge derived from previous EAF libraries as a starter. For EAF-2010 this starter knowledge was taken from the EAF-2007 file [7]. This is the sixth time that SAFEPQA-II has been used for library development rather than the SYMPAL/SAFEPQA tools [8,9,10] that were used for versions previous to 2001. Use of SAFEPQA-II has enabled the efficient and comprehensive development of the new library.

The new version contains the results of a sustained effort from many laboratories and physicists world-wide. In common with the EAF-2007 library, the current library has an upper energy limit of the data at 60 MeV. New reactions have been added to this library and the file is slightly larger than the EAF-2007 release. The point-wise library has increased from 264 Mb to 275 Mb and has also gained considerably in quality and completeness. The wide range of available integral data has been used to improve the library, although this action will continue over the next year with the planned validation exercise on EAF-2010.

EAF-2010 contains data for 99 elements from H to Fm, but excludes data for the short-lived radioactive element Fr. There are 816 target isotopes, including ground, first and second isomers, which have non-zero cross sections (*i.e.* greater than  $10^{-8}$  b) below an energy of 60 MeV. Cross sections to and from isomeric states are listed separately in a point-wise ENDF File 3 section format. This leads to a total of 66,256 reaction channels that contain data. During the creation of the library several checks were made to monitor the quality of the data. The procedures employed, forming a part of SAFEPAQ-II, are fully described in reference 2 and are summarised in Figure 1. The entire process is handled in an interactive fashion allowing new data to be input, existing data to be examined in graphical and tabular modes, modifications to be defined and validation carried out. All changes to data are automatically logged and this forms part of the quality assurance (QA) of the library.

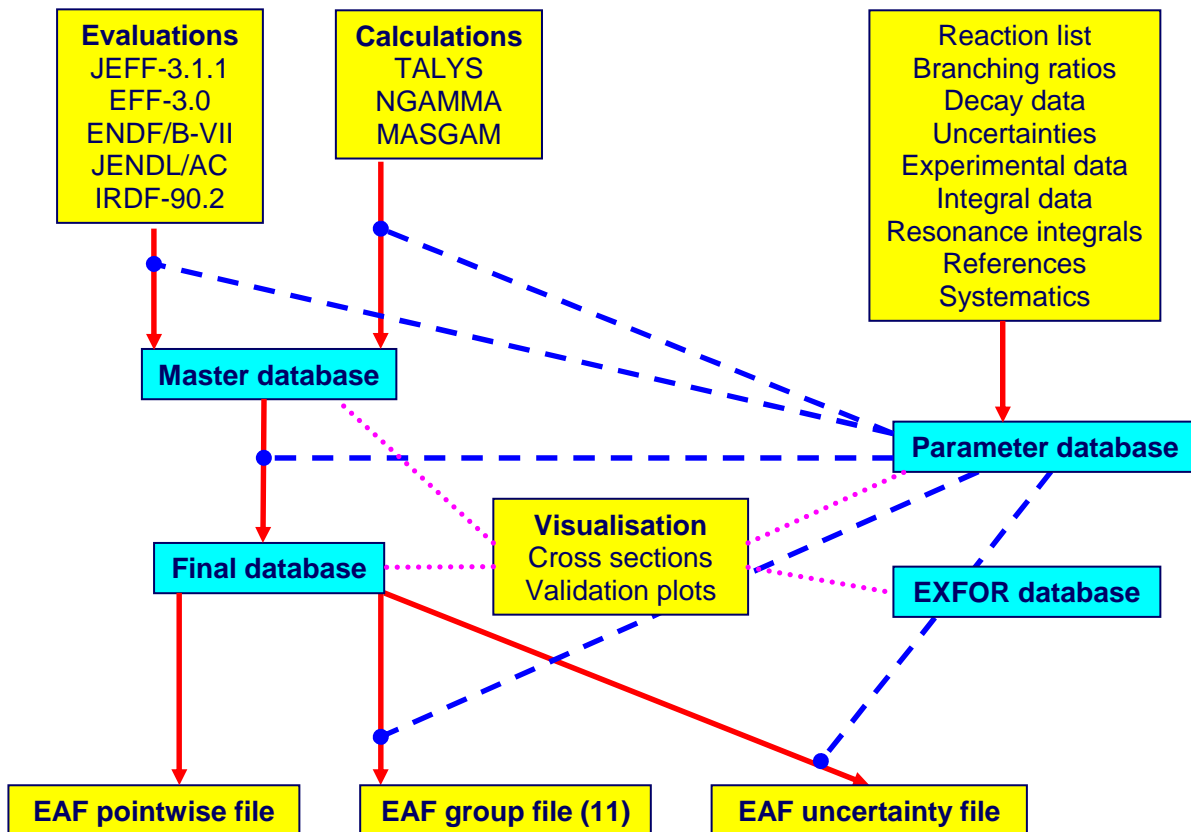

Figure 1. Flowchart of the SAFEPAQ-II processes. The arrows indicate flows of data, the dashed lines indicate that information in Parameter is required in the conversion and dotted lines show sources of data for visualisation.

## Historical survey

EAF-2010 is the latest result of a large amount of work on activation data carried out world-wide. The present section puts it in its historical context, and enables references to some of this earlier work to be given. It is interesting that if we look back over the last 30 years

and survey the questions that were being addressed by the fusion community about activation of materials in fusion devices and the tools available to give answers, it is evident that while the tools are much more extensive and sophisticated, many of the concerns are rather similar.

In the UK, the data library available for activation libraries was UKCTRIII, while the inventory code used was ORIGEN [11].

UKCTRIII was produced by Jarvis [12] from the earlier UKCTRII [13]; both these libraries were designed for fusion activation calculations. UKCTRIII was a multi-group library (100 group GAM-II) that covered the energy range thermal - 15 MeV. It contained 1,477 reactions on 305 targets (note that U and Pu isotopes were included), some of which were radioactive (all radionuclides with  $T_{1/2} > 10$  days were considered as targets). It covered only 10 reaction types, ((n,2p) and (n,n't) are the 'low-energy' reaction types missing). Reference 12 describes the data sources for the library, and while much of the library was from experimentally based sources, nearly 500 reactions were calculated by the simple model code THRESH [14]. The library contained isomeric states as daughters, but no long-lived isomeric states were included as targets.

In the early 1980s, ECN Petten<sup>†</sup> (Netherlands) was involved in work, in collaboration with JRC Ispra, on the nuclear data needs for fusion activation. Collaboration between ECN and UKAEA led to a new library UKCTRIII-AR2 [15] which contained renormalisation of a large number of the UKCTRIII cross sections to experimental data at 14.5 MeV [16] or to systematics. This library was used for a series of activation calculations, but it was recognised that it was far from complete (many stable nuclides were missing, and the radionuclides considered as targets was limited), based on simple model calculations and lacked a proper treatment of isomeric states.

In 1985 Mann *et al.* produced a new activation library - REAC [17]. This substantially increased the number of reactions to about 6,000 (although the number of targets remained at about 300). This US library was made available to ECN Petten (there was a tripartite collaboration between ECN, UKAEA and Hanford, starting in about 1986, which involved sharing of data libraries). It should be noted that REAC was a point-wise library and that the data extended to 40 MeV. Another important difference from UKCTRIII was that reactions such as (n,t) and (n,n'd) which produce the same daughter nuclide were not lumped together. This is important if accurate calculations of gas production are to be carried out.

Library development was continued at ECN by the process of renormalisation of REAC and the addition of data for radioactive

---

<sup>†</sup> The current name is NRG Petten.

targets. The new library was named REAC-ECN-1 [18]. The main features of REAC-ECN-1 were:

- An additional comment line was included in REAC-ECN-1. Note that REAC had a single comment line; apart from these lines both files are in ENDF/B-5, MF=3 format. The MT reaction identifiers are adopted except that for production of isomeric states, 300 (for m) or 600 (for n) are added.
- The GAM-II group format file GREAC-ECN-1 is similar to that of UKCTR111A except for the addition of the two comment lines. There are additional reactions so the ENDF MT numbers have been adopted, and then multiplied by 10 and the state value of the daughter added.
- The aim was to include all radionuclides with  $T_{1/2} > 1$  day as targets, in fact all the isomeric targets and a few ground state targets were missing.
- Data values at 14.5 MeV were compared with available experimental data, and renormalized if necessary.
- The branching ratios at 14.5 MeV were checked and if no reliable experimental data were available, the branching ratio was set to 0.5.
- Systematics at 14.5 MeV were taken from Qaim [19] and Kumabe and Fukuda [20]. These were used to renormalize the data from model calculations.

Further work followed at ECN leading to the release of REAC-ECN-2 [21]. This corrected some errors and introduced new systematics. The main features are:

- The systematics of Forrest [22] were adopted for production of charged daughters.
- The isomeric branching ratio was changed from 0.5 to a value determined by systematic formulae [23,24] that depend on the isomeric state spin of the daughter nuclide. Only in the case of (n, $\gamma$ ) reactions did the general value of 0.5 remain.
- Isomeric targets were included; these had the same cross sections as for the ground state.
- Some additional data sources were used for checking and renormalisation at 14.5 MeV.

The next library release by ECN was REAC-ECN-3 [25]. This contained 8,466 reactions in the energy range thermal to 20 MeV. Its main features were:

- Checking and improvement of 51 important reactions which produce long-lived radionuclides.

- Addition of 6 short-lived isotopes.

At about the same time a new library, UKACT1 [26,27], was produced by UKAEA. This was based on the same REAC library, but was only available in the GAM-II group structure. It used as a starter file GREAC-ECN-1, to which were added more targets (using THRESH) so that all radionuclides with  $T_{1/2} > 1$  day had data (in addition 34 nuclides with shorter half-life were included where a product formed by a single reaction is an important long-lived nuclide). Some features were:

- It included 49 first isomers and 4 second isomers as targets, and included all isomeric daughters with  $T_{1/2} > 1$ s.
- All targets included capture reactions (although for some radionuclides these were estimated).
- Superelastic collisions were included (these refer to (n,n') reactions from an isomeric state to the ground state).
- Checks were made to ensure that none of the standard reactions from each target were missing.
- UKACT1 contained 8,719 reactions on 625 targets.

By 1989 it was realised that it was unnecessary for such parallel library development at ECN and UKAEA to occur, so it was agreed that UKAEA would maintain the decay data library and the inventory code FISPACT, and that ECN would maintain the cross section library. UKAEA would continue to contribute to cross section development, but pass all data to ECN who would supply group libraries to UKAEA. By such collaboration an activation 'package' was developed.

This strategy led to the starter file for the European Activation File (EAF-0) [28], although it is also referred to as REAC-ECN-4 in some ECN reports. Note that this was also the first library that was assembled by the SYMPAL processing code (albeit an early version of SYMPAL with few of the features found in the final version [9]). The main improvements in EAF-0 over REAC-ECN-3 were:

- Addition of reactions on 142 targets (many of them isomers); isomeric targets had thresholds correctly different from ground state target. All targets with  $T_{1/2} > 1$  day included, giving 10,787 reactions.
- (n,n') reactions improved.
- (n,3n) cross sections near threshold adjusted.
- Renormalisation at 14.5 MeV improved.

EAF-1 (REAC-ECN-5) [29], was the first of the EAF series to be widely used in activation calculations following its release in March 1990. A clear statement of the EAF strategy is contained in a paper presented in late 1989 [30], the main points are:

1. Address the completeness of the library using the existing tools.
2. Provide the library with a simple but complete uncertainty file.
3. Carry out uncertainty estimation and sensitivity studies which will provide feedback on the quality of important reactions.
4. Wherever possible, improve the quality in general using more advanced model codes.

The main features of EAF-1 were:

- The number of targets was increased by demanding that all radionuclides with  $T_{1/2} > 0.5$  day had data.
- Improvement of low-energy data, particularly for the  $(n,\gamma)$  and  $(n,n')$  reactions.
- Inclusion of a provisional uncertainty file for important reactions covering the energy range thermal to 20 MeV.
- Use of more high quality evaluated files (*e.g.* from the JEF libraries).
- Special evaluations for 101 important reactions [30] to both long- and short-lived nuclides included.

The main emphasis for EAF-2 [31,32,33], which was released in May 1991, was to carry forward the EAF-1 improvements with special emphasis on the  $(n,\gamma)$  reactions. The main features were:

- 11,855 reactions on 699 targets.
- Use of some data from the international dosimetry file IRDF-90.
- Use of error factors derived from systematics [22] to assess the uncertainties for most of the reactions.
- Use of new data for renormalisation at 14.5 MeV.
- Group libraries in both GAM-II (100 groups) and VITAMIN-J (175 groups).

EAF-3 [34,35] was released in May 1992, the main features were:

- 12,899 reactions on 729 targets.
- Addition of 60 targets in the actinide range (At - Cm), the cross section data including the fission channel.

- Uncertainty file for all reactions in a 1 group (threshold reactions) and 2 groups (non-threshold reactions) structure.
- (n,p) and (n, $\alpha$ ) reactions with positive  $Q$ -values were inspected and revised in the thermal region.
- (n,2p) reactions calculated by THRESH were inspected and revised in the 14.5 MeV region.
- Use of more evaluated data (from EFF-2, ENDF/B-VI and JEF-2).
- Improvements in the (n, $\gamma$ ) data [36,37], including addition of the pre-equilibrium component at high energies if absent.
- Use of energy dependent isomeric branching ratios for (n, $\gamma$ ) reactions.
- Check of EAF values with experimental data at three energies (0.0253 eV, 30 keV and 14.5 MeV).

EAF-3.1 was released in mid 1993; apart from the correction of minor errors the cross section library remained the same as EAF-3, the major change was in the uncertainty file [38]. This was substantially improved, but the format remained the same.

EAF-4 [39] was released in March 1995, its main features were:

- 13,096 reactions on 734 targets.
- Addition of 25 higher actinide targets (Ra - Fm).
- Replacement of many of the data generated by THRESH with either new evaluations or superior calculations.
- Improvement of the capture reactions, especially the energy dependent isomer ratio.
- Additional comparison and renormalisation to experimental data at 14.5 MeV.
- Branching ratio systematics were improved for threshold reactions.
- Use of all available evaluated data from EFF-2.4, IRDF-90, JEF-2.2, ENDF/B-VI and JENDL-3 libraries. Use of data from the activation file ADL-3 [40].
- Special care was taken with the reactions identified as particularly important for the ITER project [41].
- The uncertainty file contained more information for (n, $\gamma$ ) and (n,f) reactions. These were given in three groups rather than the two groups used previously. More experimental uncertainties were used to replace the generic values adopted from systematics.
- The group-wise library was made available in two additional group structures - WIMS (69 groups) and XMAS (172 groups).

- The ability to calculate sequential charged particle reactions in FISPACT was due to new EAF libraries developed at FZK. See the FISPACT-2007 user manual [1] for details of these libraries.

EAF-4.1 [42] was released in June 1995. This version was the last processed at ECN Petten. It corrected various errors introduced into EAF-4.0 during processing. EAF-4.1 contained 12,976 reactions on 736 targets. Note that for distribution to users only the group-wise libraries are released, these only contained data for targets H - Cm, the higher actinide data only appearing in the point-wise library.

Work over the period 1995-1996 was devoted to the installation of SYMPAL at UKAEA and the further development of SYMPAL, SAFEPAQ and EAF that enabled the production of the IAEA FENDL/A-2.0 [43] library.

EAF-97 [44] was released in the summer of 1997. It contained data for 12,469 reactions on 766 targets. Many new data sources and experimental data [45,46,47,48,49,50,51,52,53] were used in its production. Special emphasis was put on improving the actinide data and the capture data [54]. However, erroneous interpolation laws were spotted when comparing plots of ENDF against PENDF and point-wise data against group-wise files [55]. It was decided to modify EAF-97 to correct the interpolation laws and EAF-97.1 was produced in January 1998. The corrections led to the modification of the interpolation law for 353 reaction channels in the point-wise file.

During the period 1998 - 1999, extensive data validation work was carried out. This contributed to the release of EAF-99 [56] at the beginning of 1999. It contained 12,468 reactions on 766 targets and while covering the same reactions as EAF-97.1 benefited from the large amount of integral data generated as part of the European Fusion Technology programme. About 750 reactions were significantly modified based on the integral data and experimental data from EXFOR. New data sources that were available include the Russian dosimetry file (RRDF) and helium production library (HEPRL-96) [57], individual evaluations from IRK Vienna [58] and data corrections from LANL [59].

General improvements in the  $1/v$  region for non-threshold reactions, additional calculations using NGAMMA, review of the (n,f) reactions and improvement of the uncertainty file were also areas of improvement in EAF-99.

Beginning in 1998 work started on the development of a new data evaluation and processing tool. This was designed to replace SYMPAL and SAFEPAQ and to use modern computer technology. SAFEPAQ-II [60] was designed from scratch using relational databases and interactive graphics. It runs on the various Windows operating systems and thus has the advantage of portability (it has

been installed at JUKO Research and CEA Cadarache) and of an automatic logging system that enables good quality assurance (QA) to be achieved. It is based on the ideas of SYMPAL and SAFEPAQ, but extends them and makes them more robust. A stable version was available in 2000 and it was used in the production of EAF-2001.

EAF-2001 [61,62] was produced in March 2001, although a maintenance release was also distributed in December 2001. It contained 12,470 reactions on 766 targets and benefited from the large amount of integral data generated as part of the European Fusion Technology programme. About 135 reactions were significantly modified based on the integral data and experimental data from EXFOR. New data sources that were available include the IRK evaluations of  $^{58}\text{Ni}$  [63] and  $^{60}\text{Ni}$  [64] and calculations by Mengoni [65] on light nuclides. A new systematic for  $(n,\gamma)$  at 30 keV was used. The use of integral data to improve the activation libraries was becoming increasingly important. EAF-2001 was the first to have a formal validation report [66,67] bringing together all the currently available integral data in the form of effective cross sections and comparing these with the library values.

New data sources, experimental and integral data were all incorporated in SAFEPAQ-II and the system was developed and tested further during 2001-2002; the outcome of this work, in respect of the neutron-induced cross section library, was the release of EAF-2003 [68]. It contained 12,617 reactions on 774 targets, and the most significant improvement resulted from the comparison of integral data with EAF-2001 [66]. A new systematic for  $(n,n'\alpha)$  was used [66], an improvement on the approximation used in earlier libraries. Several new data sources [69,70,71,72,73] were available for data selection. Considerable effort was spent on the  $(n,\gamma)$  channel, including the representation of missing resonances by the Single Resonance Approximation (SRA) [2] for about 80 reactions. Reactions on actinide targets was another area of improvement, including SRA for  $(n,f)$  reactions on five targets and changes of data source. About 77% of the actinide target reactions were modified using SAFEPAQ-II. Another innovation for EAF-2003 was a Quality score for each reaction indicating the experimental support for the reaction due to both differential and integral data.

Although the EAF format is very convenient for use in activation codes such as FISPACT, there are advantages to having data in a standard ENDF format. To answer this need EAF-2003 was converted to ENDF format and in this format was also adopted as the activation file for JEFF-3 [74]. The reasons for the conversion into ENDF-6 format are threefold. First, it significantly enhances the JEFF-3 release by the addition of an activation file. Second, to considerably increase its usage by using a recognized, official file format, allowing use of existing processing codes and third to move towards a

universal nuclear data file in contrast to the current separate general and special purpose files. The format chosen for the JEFF-3.0/A file uses reaction cross sections (MF-3), cross sections (MF-10) and multiplicities (MF-9). Having the data in ENDF-6 format allows the ENDF suite of utilities and checker codes to be used alongside many other utility, visualizing and processing codes. By the change of format the scope of application is widened from fusion to include fission, dosimetry, inventories, depletion-transmutation and geophysics. The next step is to include the EAF uncertainty data for all channels into JEFF-3.0/A

All EAF libraries up to EAF-2003 have data in the energy range up to 20 MeV. This value is sufficient for activation calculations in fusion devices, but an increasingly important concern is the design of the IFMIF materials test facility. IFMIF [75] is an accelerator-based d-Li neutron source that will give a neutron spectrum with a high-energy tail up to about 55 MeV. In order to include such high energy neutrons in activation calculations it was necessary to extend the energy range of the EAF libraries. This was a major task, and prior to the production of the EAF-2005 library, there was a test library, EAF-2004 [76], produced to demonstrate the various methods, that was not distributed to users. Further information on this 'proof-of-principal' library is available in reference 77.

EAF-2005 [78,79] was released at the beginning of 2005. As mentioned above it was a significantly larger file than previously released as the pointwise data extended to 60 MeV (and the groupwise data to 55 MeV). It contains data for 62,637 reactions on 775 targets. The library size was 254 MB (compared to 128 MB for EAF-2003). It had been demonstrated in the production of the EAF-2004 test file that it was feasible to retain the existing EAF methodology. Specifically reactions continued to be described by MT numbers rather than the production of various amounts of daughter nuclides. Additional (non-ENDF standard) MT values were defined with the consequence that 86 reaction types were used in EAF-2005 compared to the 23 previously.

For reactions present in EAF-2003 it was decided to extend the data by using data generated with the TALYS model code [80] by A. Koning with global parameters. SAFEPAQ-II did this task automatically, renormalizing the high energy data so that it fitted smoothly with the EAF-2003 data at 20 MeV. In some cases the necessary data were not available from TALYS, in which case other data were used. Secondly, reactions not present in EAF-2003 but with threshold below 60 MeV and values above a minimum (1  $\mu$ b) were added to the reaction list. Another consequence of the extended energy was the need to extend the number of uncertainty groups so that non-threshold reactions had four while threshold reactions had one or two depending on the threshold energy.

A number of new data sources were available:

- Evaluations by the CEA Bruyeres le Chatel on Eu [81] and Rh [82] isotopes,  $^{151}\text{Sm}$  and  $^{238}\text{U}$  [83].
- The latest release of the US library, ENDF-B/VI release 8.
- The preliminary release of the US library, ENDF-B/VII.
- The intermediate energy library IEAF-2001 [84].
- The European JEFF-3.0 library [85].
- Maslov data for actinides [86].
- Calculations by V. Avrigeanu *et al.* for Mo isotopes [87].
- The calculated library NRG-2003 prepared using TALYS [88].
- The calculated library TALYS-5 prepared by A.J. Koning covering the same range of targets as EAF.

The fivefold increase in the number of reactions meant that it was inevitable that some errors were present in EAF-2005. These became apparent during the integral validation and after investigation with the new method of statistical analysis of cross sections (SACS) which is described in detail in a later section. Consequently data for 250 reactions were changed and a maintenance release, EAF-2005.1 was distributed at the beginning of 2006. This also contained a preliminary deuteron-induced cross section library [89].

EAF-2007 [7] was released at the beginning of 2007. It was produced as the second generation of the high energy version of the activation file, extending to 60 MeV, and so benefited from the user feedback from the first release. The library extension to higher energy was tested thoroughly, demonstrating its usefulness and allowing much needed scooping studies to be carried out in the high energy region. It contains data for 65,565 reactions on 816 targets, the library size was 264 MB. The new data sources available were:

- The latest beta release of the US library, ENDF-B/VII.
- The European JEFF-3.1 library [121].
- Calculations by V. Avrigeanu *et al.* for  $^{181}\text{Ta}$  and Hf isotopes [177].
- The calculated libraries TALYS-6 and TALYS-6a prepared by A.J. Koning.
- Evaluations by P. Pererslatsev *et al.* for W isotopes [178].
- The dosimetry library IRDF-2002 released by the IAEA [179].
- The JENDL high energy file [180]
- Files produced by the WPEC subgroup 23 for fission products [123].

Further discussion on the methods used to produce the EAF-2010 library are given in later sections along with description of new data sources used in EAF-2010, such as the inclusion of new TALYS-derived data and experimental data.

## Calculational tools

The preferred source of cross section data is one of the evaluated files. However, for many nuclides (especially radioactive ones) no such source is available and cross sections must be calculated. The code THRESH [14] has been mentioned in the previous section and this was widely used in earlier versions. Another simple model code, suitable for mass-production runs, EXIFON [90], has been also used in earlier EAF versions for the threshold reactions  $(n,2n)$ ,  $(n,3n)$ ,  $(n,p)$  and  $(n,\alpha)$ . Both codes are however, very unsophisticated and a wider range of tools are now preferred. In fact only two reactions remain from EXIFON, the rest have been changed in EAF-2010 to use data calculated with the TALYS code.

Many of the older neutron-capture codes (FISPRO, MASGAM [91], MASGAM+SIG-ECN and NGAMMA [92]) are still applicable and results from them still used for some for  $(n,\gamma)$  reactions. NGAMMA was used for many reactions in EAF-2001, -2003, -2005, -2007 and is still used for some reactions in EAF-2010, although as improvements are made to the data TALYS data are being increasingly used. The NGAMMA code is described below for completeness.

Two approximations applied in the low energy resonance region for reactions with no threshold (such as  $(n,\gamma)$ ,  $(n,f)$ ,  $(n,p)$  and  $(n,\alpha)$ ) are outlined below. The Single Reaction Approximation (SRA) is described in an appendix of the SAFEPAQ-II manual [2]; its ability to describe resonance integrals is demonstrated below. The Low Energy Approximation (LEA), used for  $(n,p)$  and  $(n,\alpha)$  reactions is also described.

The main calculational tool now is the code TALYS [80], which was first used to a limited extent for EAF-2003, but which has become of major importance for the new high-energy data above 20 MeV. For EAF-2010 the results of global calculations with TALYS code, labelled as the TALYS-6 and TALYS-6a data sources, have been used by default for all threshold reactions where there are no experimental data below 20 MeV. For such reactions renormalisation to systematics is only applied for a limited number of  $(n,p)$  and  $(n,\alpha)$  reactions. As noted above data from these sources are used to provide data for all reactions with thresholds above 20 MeV. In general, for an increasing number of reaction channels, TALYS is now also used for data below 20 MeV. The TALYS code is also described below. The TALYS code is also described below.

### NGAMMA

NGAMMA is based on the spherical optical model, the Hauser-Feshbach formula with width fluctuation correction, the exciton model [93] and the unified model [94] in which equilibrium and pre-

equilibrium emission mechanisms are unified and angular momentum conservation is taken into account. This exact treatment of pre-equilibrium processes replaces the approximation by systematics as applied in MASGAM. Besides the radiative capture channel the code also handles the competing particle emissions, including neutrons, protons and alphas. The possibility to renormalize the calculation to experimental data or to systematics is maintained.

The main input parameters are:

- **E1, M1 and E2 strength function models and giant resonance parameters.** The generalized Lorentzian formulation [95] has been adopted for the E1 resonance, except for deformed nuclei in the mass range above  $A = 150$ , for which the classical Lorentzian was used (based on conclusions in references 96 and 97). The giant E1 resonance parameters have been taken from a recent report [98] and checked against the very recent compilation of Varlamov [99]. If the experimental data on the E1 giant resonance were missing, the value from the neighbouring target has been extrapolated. The spin-flip M1 resonance has been adopted for M1 radiation with the standard parameterization [95], the cross section  $\sigma_0$  has been renormalized against the systematics (for details see reference 92). The single-particle model is used for E2 radiation.
- **Optical model.** Standard global neutron optical model parameters of Moldauer [100], Wilmore-Hodgson [100], Buck-Perey [101,102] and Uhl [103] have been tested on several nuclei ranging from  $A = 90 - 205$  and the parameters of Uhl, giving the best results, were finally adopted for calculations.
- **Discrete levels and level density.** Discrete levels have been taken from corresponding compilations published in Nuclear Data Sheets. The newly evaluated set of BSFG (back shifted Fermi gas) level density model parameters of the Beijing group (recommended by the IAEA RIPL/CRP) [104,105] have been used. In cases where no data were available, an extrapolated estimate from systematics was applied.

---

## SRA

The Single Resonance Approximation was introduced in EAF-2003. The physical idea was to represent the large thermal cross section ( $> 10$  b) of some reactions by one strong resonance superimposed on a  $1/v$  background. The advantage of this method is the possibility it gives to reproduce the resonance integral in a better way than the  $1/v$  component alone. A full description of the method is given in Appendix 5 of the SAFEPAQ-II user manual [2].

## LEA

The Low Energy Approximation (LEA) is a method of adding resonance data to (n,p) and (n, $\alpha$ ) reactions based on the resonances in the (n, $\gamma$ ) file. A full description of this method is given in Appendix 6 of the SAFEPAQ-II user manual [2].

## TALYS

TALYS [80, 170] is a computer code system for the prediction and analysis of nuclear reactions. TALYS simulates reactions that involve neutrons, gamma-rays, protons, deuterons, tritons, helions, alpha-particles and fission, in the 1 keV - 200 MeV energy range and for target nuclides of mass 12 and heavier. This is achieved by implementing a suite of nuclear reaction models into a single code system. It enables the evaluation of nuclear reactions from the unresolved resonance region up to intermediate energies. Generally TALYS can be used in two distinct ways:

- Carry out a very detailed calculation with various adjusted parameters and choices for nuclear models, so that specific experimental data for one target nucleus are reproduced.
- For the large scale, default calculations for many nuclides, in which case adjustment to experimental data is impossible or, for the moment, not practical.

While the first method is generally used for detailed isotopic evaluations, it is clear that for activation libraries with many thousands of reactions the second method must be used.

All results are created using a script which runs TALYS with default input parameters. This means that the data from such a calculation have not been tested against individual experimental data for each isotope, therefore they are only as good as the global parameters available as input to the TALYS code.

The main nuclear models and methods used in TALYS are:

*Optical model* calculations are performed with the optical model potentials (OMP) of Koning and Delaroche [106]. For *compound*

*nucleus* reactions the model of Moldauer, i.e. the Hauser-Feshbach model corrected for width fluctuations, is used.

*Coupled-channels* calculations are automatically invoked when a coupling scheme is available. For the *level density*, the composite formula proposed by Gilbert and Cameron, consisting of a constant temperature law at low energies and a Fermi gas expression at high energies is applied.

Energy-dependent *shell effects* are included. Gamma-ray *transmission coefficients* are generated with the Kopecky-Uhl generalized Lorentzian for strength functions. For *pre-equilibrium* reactions, which become important for incident energies above about 10 MeV, the two-component exciton model is used. Multiple pre-equilibrium emissions up to any order of particle emission is included.

Further details on TALYS and how to obtain it can be found at the website [www.talys.eu](http://www.talys.eu).

## The Master database

The library development tool SAFEPQAQ-II contains several relational databases that contain data required in the construction of the EAF libraries. The Master database contains data for each required reaction taken from the original data sources, in cases where the reaction is split but the original data are for the total, the total is used for each split reaction. The data thus require many modifications to be carried out systematically before they can be used in EAF. Each original data source was converted into a source database and it is the entries in the source databases that are selected and used in Master.

The sequence of modifications that is applied to Master in the process of producing the Final database is fully described in the SAFEPQAQ-II User manual [2]. These include the checking of  $Q$ -values and thresholds, identification of reactions with suspect interpolation laws and removal of data points above 60 MeV. The branching and renormalisation are largely automatic, using data in the tables of the Parameter database. This contains all the relevant decay data extracted from the EAF decay data library such as isomeric spins. Spins are required during the branching process and SAFEPQAQ-II automatically ensures that these are consistent in the decay and cross section libraries.

The original data in Master are not changed in any way; all modifications are applied to a copy held in Final. This means that the Master data are available at any time to be visualised; they can be compared with EXFOR data, other data sources and with Final data as the various modifications are progressively applied. If a new data source is required for a particular reaction there are tools available in

SAFEPAQ-II to change the source in Master, create the modifications and apply these to generate the Final data.

## The Parameter database

The Parameter database contains all the information that describes a particular version of an EAF library. The list of reactions and their sources that is included in the library, the list of nuclides, their sources and properties and the set of experimental information that can be used to renormalize or split a particular cross section. These values are stored in a series of tables that are described fully in reference 2, but the most important are listed below to show the range of data.

- Energy boundaries of the group schemes.
- Systematic branching ratios as a function of spin.
- Decay data for all nuclides.
- Systematic error factors for reaction types.
- Experimental data at 25.3 meV, 30 keV and 14.5 MeV.
- Integral data in various neutron spectra.
- Log of all data changes.
- Pre-modifications and modifications.
- List of nuclides contained in libraries.
- List of reactions contained in libraries.
- Literature references.
- Resonance integral data.
- Neutron spectra data.
- Cross section systematics.
- Summaries of data in Final.
- Uncertainty data.
- Nuclide masses from Wapstra.
- Known biological hazard,  $A_2$  and clearance values.
- Details of the progress of library processing.

## Cross section systematics

Cross section systematics at various energies are algebraic formulae derived from the analysis of experiments that provide a type of 'semi-experimental' information. They can be used to judge the quality of calculated or evaluated excitation curves and where experimental data are absent can also be used for renormalization. Work on testing of EAF-2007 and EAF-2010 using the SACS methodology has led to new insights on the validity of the systematics. Some of the basic observations and recommendations are listed below:

**14.5 MeV systematics** - If the 14.5 MeV energy range is close to or at the maximum of the excitation curve,  $\sigma_{\text{sys}}$  can be safely used for validation as well for the SAFEPAQ-II renormalization modifications

(RN-SYS). However, for many reaction channels for heavier mass targets or for targets with large asymmetries, the 14.5 MeV energy range is in the beginning of the steeply raising part of the excitation curve and in such cases  $\sigma_{\text{sys}}$  should be used only for comparison with the library data but never for renormalization. Based on this argument, the following recommendations are made concerning restrictions for renormalization of the major reactions channels:

- (n,2n), (n,n'p) and (n, $\gamma$ ) for all masses,
- (n,p) and (n, $\alpha$ ) reactions for targets with  $A > 130$  should always be checked against the  $\sigma_{\text{max}}(s)$  SACS analysis,
- (n,d) reaction only for targets with  $s \leq 0.1$
- (n,n' $\alpha$ ), (n,t), (n,h) and (n,2p) not at all.

**30 keV (n, $\gamma$ ), 3 MeV (n,n')** and **20 MeV systematics** can be used only as indicative information for eventual modifications. The uncertainty factors of these systematics are large ( $\geq 100\%$ ).

**Use of RN-SYS in EAF-2010** – The usage of this modification for EAF-2010 was less than in previous libraries. It was also used selectively for a large number of (n,p) and (n, $\alpha$ ) reaction data in order to decrease the slight systematic overestimation noted in the TALYS calculations. Again, this was always done in combination with the  $\sigma_{\text{max}}(s)$  SACS analysis.

## 14.5 MeV systematics

The SAFEPAQ-II code contains information on the systematic formulae at 14.5 MeV; these are listed below for reference.

In the formulae below,  $s$  is the asymmetry parameter of the target nuclide =  $(N-Z)/A$  and all the cross sections are in mb. Note that the (n,2p) formula was new for EAF-2001 and the (n,n' $\alpha$ ) formula was new for EAF-2003. Starting with EAF-2005, SAFEPAQ-II contains the option to use either the standard or an alternate set of systematics for the (n,n'p+d) and (n,t) reactions. This is noted below where the alternate formula is given. The standard formula can be found in the EAF-2003 report [68].

### (n,p)

The systematics of Forrest [22] and Doczi *et al.* [107] are used:

$$\sigma_{np} = 7.657(A^{1/3} + 1)^2 \exp(-28.80s - 59.24s^2 + 0.2365A^{1/2}) \quad Z \geq 40$$

$$\sigma_{np} = 23.659(A^{1/3} + 1)^2 \exp(-23.041(s + s^2)) \quad Z < 40$$

**(n,α)**

The systematic of Majdeddin *et al.* [108] is used:

$$\sigma_{n\alpha} = 15.0678(A^{1/3} + 1)^2 \exp(-27.55(s + s^2))$$

**(n,d+n'p), (n,d) and (n,n'p)**

The systematics of Forrest [22], Kopecky [109] and Konobeyev [110] are used:

For light nuclei: ( $s \leq 0.125$ )

$$\sigma_{nd} = 9.94 \exp(-0.11s)$$

$$\sigma_{mp+d} = 900.9(A^{1/3} + 1)^2 \{1 - 0.4828 \tanh(\xi + 1)\} \exp(-52.3s - 135.7/A)$$

For heavy nuclei: ( $s > 0.125$ ). Note that for  $\sigma_{nd}$  the alternate form is shown.

$$\sigma_{nd} = 53.066(A^{1/3} + 1)^2 A^{-1/3} (-1.912s + 0.011134Z/A^{1/3} + 0.30797)^3$$

$$\sigma_{mp+d} = 900.9(A^{1/3} + 1)^2 \{1 - 0.4828 \tanh(\xi + 1)\} \exp(-52.3s - 135.7/A)$$

$\xi$  is the difference between the proton and neutron separation energies.

Finally  $\sigma_{mp}$  is for both cases calculated as  $\sigma_{mp} = \sigma_{mp+d} - \sigma_{nd}$

If this formula has a value less than or equal to zero then the following alternative is used:

$$\sigma_{mp} = 0.1\sigma_{nd}$$

**(n,t)**

The systematic of Konobeyev [110] is used; note the units are  $\mu\text{b}$  and that the alternate form is shown:

$$\sigma_{nt} = 53066(A^{1/3} + 1)^2 A^{-1/3} (-0.35627s + 0.0045118ZA^{-1/3} + 0.047995 + \Delta)^3$$

with  $\Delta = 0$  for even-even target nuclei,

$$\Delta = 4.7774A^{-3/4} - 1.0881A^{-1/2} \text{ for odd } A \text{ target nuclei and}$$

$$\Delta = 9.5548A^{-3/4} - 2.1762A^{-1/2} \text{ for odd-odd target nuclei.}$$

**(n,n'd)**

An approximate value is used; note that the standard form for (n,t) is used:

$$\sigma_{nd} = 0.1\sigma_{nt}$$

Thus using the formula given in reference 68:

$$\sigma_{nd} = \begin{cases} 0.1516(A^{1/3} + 1)^2 \exp(-24.35s + 0.2670A^{1/2}), & A \text{ even} \\ 440.21 \exp(-20.509s), & A \text{ odd} \end{cases}$$

### **(n,h)**

The systematic of Lishan *et al.* [111] is used, note the units are  $\mu\text{b}$ :

$$\sigma_{nh} = 0.75(A^{1/3} + 1)^2 \exp(-11.338s)$$

### **(n,n')**

The systematic of Vonach [24] is used. This is held as a table of values for various isomeric spins, and no analytic formula is presented.

### **(n, $\gamma$ )**

The systematic of Kopecky *et al.* [29] is used:

$$\sigma_{n\gamma} = 1.18 - 1.13 \exp(-0.01338A)$$

### **(n,2n)**

The systematic of Badikov *et al.* [114] is used, note that this is only valid if  $A \leq 210$ :

$$\sigma_{n2n} = 47.015(A^{1/3} + 1)^2 (1 - 3.9777 \exp(-24.116s))$$

### **(n,2p)**

The systematic of Kopecky [61] is used, note the units are  $\mu\text{b}$ :

$$\sigma_{n2p} = 48.49 \exp(-2.99s)$$

Note that recent experimental data suggests that most previously available data were upper estimates and thus the systematic is overestimated. Consequently it was not used for renormalisation in EAF-2007, but was still used for validation.

### **(n,n' $\alpha$ )**

The systematic of Kopecky [68] is used:

$$\sigma_{n\alpha} = 17.48 \exp(-24.2s)$$

### 3.0 MeV systematics

#### $(n,n')$

The systematic of Shimizu *et al.* [112] is used:

$$\sigma_{nn'} = (A^{1/3} + 1)^2 \exp(-0.110\Delta^2 + 0.0.686\Delta + 4.21)$$

where  $\Delta$  is the difference between the isomer and ground state spins ( $J_m - J_g$ ). This systematic was introduced in EASY-2007.

### 20.0 MeV systematics

The systematics of Konobeyev [110] are used and can be applied for  $A > 40$  target nuclei. They have been obtained on the basis of calculated cross sections for 245 stable nuclei with  $40 < A < 209$ .

#### $(n,n'p)$

$$\sigma_{nnp} = 53.066(A^{1/3} + 1)^2 \{ A^{-1/3}(-2.7098(s + 1.5/A) + 0.67115)^2 + \exp[-496.74(s + 1.5/A)^2 + 48.162(s + 1.5/A) - 1.6714] \}$$

#### $(n,p)$

$$\sigma_{np} = 53.066(A^{1/3} + 1)^2 \exp[-47.384(s + 1/A)^2 - 2.3294(s + 0.5/A) - 0.10405Z/A^{1/3} - 2.3483] \text{ if } Z < 50$$

$$\sigma_{np} = 53.066(A^{1/3} + 1)^2 (-1.2477(s + 1/A) + 0.4087)^3 \text{ if } Z \geq 50$$

#### $(n,d)$

$$\sigma_{nd} = 53.066(A^{1/3} + 1)^2 A^{-1/3} (-1.3107s + 0.0019167Z/A^{1/3} + 0.48491)^3$$

#### $(n,t)$

Note the units are  $\mu\text{b}$ ,

$$\sigma_{nt} = 53066(A^{1/3} + 1)^2 A^{-1/3} (-0.1506s + 0.000306ZA^{-1/3} + 0.19566 + \Delta)^3$$

with  $\Delta = 0$  for even-even target nuclei,

$$\Delta = 0.89317A^{-3/4} - 0.10839A^{-1/2} \text{ for odd } A \text{ target nuclei and}$$

$$\Delta = 1.78634A^{-3/4} - 0.21678A^{-1/2} \text{ for odd-odd target nuclei.}$$

#### $(n,\alpha)$

$$\sigma_{n\alpha} = 53.066(A^{1/3} + 1)^2 \exp[-37.317(s + 1/A)^2 - 7.2027(s + 0.5/A) - 0.22669Z/A^{1/3} - 2.027] \text{ if } Z < 50$$

## 30.0 keV systematics

The SAFEPAQ-II code contains information on the systematic formula at 30 keV for the (n,γ) reaction, this was a new systematic for EAF-2001 derived by Kopecky. Details of its derivation are presented in reference 61 and 172.

### (n,γ)

The systematic of Kopecky is used:

$$\sigma_{n\gamma} = C_1(aU)^{C_2}$$

Values of  $a$  are stored in a table in the Parameter database for various values of number of neutrons ( $N$ ).  $U$  is defined in terms of the  $Q$ -value and the pairing energies by  $U = Q(n, \gamma) - P(Z) - P(N)$ . The pairing energies are given in the same Parameter table. Values of the fitting parameters  $C_1$  and  $C_2$  depend on whether the number of protons ( $Z$ ) is odd or even.

$$C_1 = 8.236 \times 10^{-8}, C_2 = 4.827 \quad Z \text{ odd}$$

$$C_1 = 6.995 \times 10^{-7}, C_2 = 4.287 \quad Z \text{ even}$$

## Non-elastic systematic

The SAFEPAQ-II code contains information on the systematic formula for the non-elastic cross section for incident neutrons with energies between 1 and 50 MeV.

In the formula below,  $A$  is the target mass,  $E$  is the neutron energy in MeV and the cross section is in mb. Note that this formula was new for EAF-2005.

The systematic of Chatterjee *et al.* [113] for  $1 \leq E \leq 50$  MeV is used:

$$\sigma_{\text{nonel}} = (31.05A^{-1/3} - 25.91)E + 342A^{1/3} + 21.89A^{2/3} + (0.223A^{4/3} + 0.673A^{2/3} + 617.4) / E$$

## Error factors

Related to the systematic formulae are values of the error factor ( $f$ ) which quantify how well the systematic fits the experimental data. The error factor derived from the systematics is used in the generation of the uncertainty file if no experimental data are available. Table 1 lists the error factors used in SAFEPAQ-II. Several factors have been reduced (indicated by \*) for this EAF-2010 release in comparison with EAF-2007.

Table 1. Error factors derived from systematics.

Reaction	Systematic	Error factor ( <i>f</i> )
(n,n')	Vonach [24]	2.0
(n,2n)	Badikov [114]	1.4
(n,3n)	Estimate	1.8*
(n,4n)	Estimate	2.0*
(n,n'α)	Estimate	2.0*
(n,d)	Forrest [22]	2.0*
(n,n'p)		2.0
(n,t)+(n,n'd)	Forrest [22]	1.6
(n,n't)	Estimate	3.0*
(n,n'h)	Estimate	3.0*
(n,f)	Estimate	2.0
(n,γ)	Kopecky [29]	1.5
(n,p)	Forrest [22]	1.5
(n,h)	Lishan [111]	1.9
(n,α)	Madjeddin [108]	1.6
(n,pα)	Estimate	3.0
(n,2p)	Estimate	3.0
(n,n'2p)	Estimate	3.0
(n,2α)	Estimate	3.0
(n,3α)	Estimate	3.0
(n,2np)	Estimate	3.0
(n,2nd)	Estimate	3.0
(n,pd)	Estimate	3.0
(n,pt)	Estimate	3.0
(n,dα)	Estimate	3.0
(n,3nα)	Estimate	3.0
(n,3n'p)	Estimate	3.0
(n,n'2α)	Estimate	3.0
(n,d2α)	Estimate	3.0
(n,t2α)	Estimate	3.0
(n,n'3α)	Estimate	3.0
(n, n'd2α)	Estimate	3.0
(n, n't2α)	Estimate	3.0
(n,2n2α)	Estimate	3.0
(n,2n'α)	Estimate	3.0
All remaining 'high-energy' reactions	Estimate	3.0

\*modified error factor in EAF-2010

## Branching ratio

The splitting of a total cross section between isomeric daughters is a major data adjustment task carried out by SAFEP AQ-II. If at least two experimental values are available at 14.5 MeV (out of a total of three:

$\sigma_{tot}$ ,  $\sigma_g$  and  $\sigma_m$ ), then the branching ratio can be deduced and applied to the total cross section.

Table 2. Branching ratio ( $b = \sigma_m/(\sigma_g + \sigma_m)$ ) as a function of the isomeric state spin ( $J_m$ ).

$J_m$	Single-particle emission at 14.5 MeV	(n, $\gamma$ ) reaction at 0.0253 eV	Multi-particle emission at 14.5 MeV
0	1.90E-01	4.20E-01	1.40E-01
0.5	2.40E-01	5.00E-01	2.00E-01
1	3.10E-01	6.00E-01	3.10E-01

20	3.52E-06	3.83E-07	3.35E-05

In cases where no experimental information on cross sections to ground or isomeric state is available, branching ratio systematics are used. The original systematics of neutron-induced isomer cross section ratios at 14.5 MeV [23], based on simplified GNASH calculations have been revised. This revision was based on recent experimental data and results of model calculations [115,116,117]. It is applied to all threshold reactions at 14.5 MeV. The new recommended values are listed in columns 2 and 4 of Table 2.

In order to account more accurately for the specificity of the branching ratio for radiative capture (thermal and resonance regions) and its strong energy dependence, the following approach has been adopted. Two branching ratios, one for the thermal and resonance range ( $b_L$ ) up to energy  $E_H$  (end of resolved resonance range) and one for the high-energy range ( $b_H$ ), have been adopted.

For the low-energy range all available experimental data at thermal energies were used and the derived branching ratio was assumed representative for this energy range. Further systematics have been derived from these data by a simple eye-guide procedure [118] and the recommended values are given in column 3 of Table 2.

For the smooth high-energy part, starting from the energy  $E_H$ , the systematics for one-particle emission in Table 2 have been used. The energy dependence of the branching ratio for (n, $\gamma$ ) systematics has been introduced in the following way. The value of  $b_L$  is kept constant up to  $E_H$  and then linear interpolation is used to connect with the  $b_H$  value at 14.5 MeV. This approach has been tested against a few rigorously evaluated branching ratios [115,116,117] produced with the code GNASH and there is reasonable agreement.

## Q-values

The procedure which calculates the reaction  $Q$ -values and energy threshold uses data from the Audi-Wapstra mass-excess table [119]. This table covers 2,655 nuclei and is supplemented with the Duflo-Zuker empirical mass formulae [120] when the nuclei do not exist in the table (for 64 nuclei). It should be noted that SAFEP AQ-II generates  $Q$ -values and threshold energy modifications automatically.

## High-energy data

### Introduction

Versions of EAF prior to EAF-2005 were developed primarily for use in calculations of fusion devices. For such applications the upper energy limit of 20 MeV is sufficient. However, it has been recognised that the materials testing that is foreseen as necessary in parallel with ITER, using proposed devices such as IFMIF [75], means that this energy limit needed to be raised – this was done for EAF-2005. The IFMIF facility will be a d-Li device with deuterons accelerated to 40 MeV impinging on a flowing Li target and generating an intense neutron field by a stripping reaction. It is expected that the neutron spectrum will contain a significant number of neutrons above 20 MeV, probably as high as 55 MeV. To enable activation calculations to be carried out for IFMIF, EAF needed to be extended to handle neutrons with energies  $> 20$  MeV.

The first decision to be made was the value of the new upper energy. By limiting this to 60 MeV it was judged possible to retain the same methodology as previously used. Such an energy is adequate for IFMIF but would not be large enough for applications such as incineration of nuclear waste using accelerators. Since IFMIF was the primary application this limit was judged suitable and this value is also used within the EFDA, F4E specification of the work. At energies above 20 MeV many new reaction types involving the emission of multiple particles are possible. Enumerating all these explicitly becomes impractical as the energy becomes too large. It was demonstrated with EAF-2005 that the use of a limited number of new reaction classes for EASY was feasible, and the same format is used for EAF-2007 and EAF-2010.

Although there are some measurements and evaluated libraries with data  $> 20$  MeV, these are rather sparse and for a source of cross section data at high energies it is necessary to rely on calculation. For this we have rely on the TENDL [175] library produce by the TALYS code system [170]. This is a very versatile system enabling the production of a wide range of data using a unified set of models but also formats.

Table 3. High energy reaction type in EAF-2010

Reaction type	MT number	Reaction type	MT number
(n,2nd)	11	(n,5nd)	170
(n,n'3 $\alpha$ )	23	(n,6nd)	171

(n,n't2 $\alpha$ )	36	(n,5nt)	174
(n,3np)	42	(n,6nt)	175
(n,n'2p)	44	(n,2nh)	176

Reaction type	MT number	Reaction type	MT number
(n,n'pα)	45	(n,3nh)	177
(n,3α)	109	(n,4nh)	178
(n,t2α)	113	(n,3n2p)	179
(n,d2α)	114	(n,3n2α)	180
(n,pd)	115	(n,3npα)	181
(n,pt)	116	(n,dt)	182
(n,dα)	117	(n,n'pd)	183
(n,5n)	152	(n,n'pt)	184
(n,6n)	153	(n,n'dt)	185
(n,2nt)	154	(n,n'ph)	186
(n,tα)	155	(n,n'dh)	187
(n,4np)	156	(n,n'th)	188
(n,3nd)	157	(n,n'tα)	189
(n,n'dα)	158	(n,2n2p)	190
(n,2npα)	159	(n,ph)	191
(n,7n)	160	(n,dh)	192
(n,8n)	161	(n,hα)	193
(n,5np)	162	(n,4n2p)	194
(n,6np)	163	(n,4n2α)	195
(n,7np)	164	(n,4npα)	196
(n,4nα)	165	(n,3p)	197
(n,5nα)	166	(n,n'3p)	198
(n,6nα)	167	(n,3n2pα)	199
(n,7nα)	168	(n,5n2p)	200
(n,4nd)	169		

The newly allocated MT numbers, from 151 to 200, allow describing reactions with up to 8 emitted particles and correspond to a set of unallocated number in the ENDF-6 format.

## EAF-2010 production

### Data origin

EAF-2010 was generated starting with the information present in EAF-2007. Data were then changed based on new sources and experimental data. The new data sources available are:

- The latest release of the US library, ENDF-B/VIIa.
- The latest European JEFF-3.1.1 library [121].
- The calculated libraries TENDL-2009 [175] and TALYS-6a covering an even wider range of targets than EAF.
- The JENDL/AC and beta release of JENDL-4 [122].
- Files produced by different CRP and WPEC subgroups [123].

### Summary of reaction types

It is useful to show how the reactions in the library can be divided into different categories; a number of relevant statistics are given in this section. Firstly, the data origin - the neutron cross sections included in EAF come from numerous sources having varying levels of quality and formats.

It will be noted that in Table 4 some sources contain (MDF) in the label, e.g. JEF-2.2(MDF). Usually it is possible to reproduce data in EAF-99 by using the original data source and then applying the standard modifications. However, in a few cases changes have been made in previous EAF versions that are not fully documented. In these cases data have been extracted from the EAF-99 MDF (Master Data File).

<b>Total</b>	<b>66256</b>

The entire EAF-2010 reaction list is given in Appendix 4. It contains target and daughter state, data origin information, Quality scores, types of modifications and the number of data points for each reaction stored in the EAF-2010 point-wise file.

Secondly, the reaction types - 86 different reaction types can be found in EAF-2010 and these are listed in Table 5. There is a very large increase over the 23 types in EAF-2003. All kinematically allowed reactions below 60 MeV are specified for each target isotope, 691 more reaction than in EAF-2007. These include threshold reactions as well as certain break-up channels on light nuclei. 816 target isotopes, for which all the major reaction types exist, are present in the file.

If new, *i.e.* short-lived or exotic, isotopes are to be included as targets, it is important to ensure that data are included for all the major channels. As a general rule including data for only a subset of the reaction channels is of limited use, and can lead to incorrect conclusions when used for inventory calculations.

### **EAF-2010 (n, $\gamma$ ) reaction**

Improvements to the neutron capture data have been concentrated in the following areas:

- Changing the data source and improving  $E_V$  and  $E_H$  values

- Improved  $1/\nu$  region renormalisation based on C/E data.

It is useful to show how the  $(n,\gamma)$  reactions can be divided into different categories, and a number of statistics are given in this section. Firstly, the final states of the EAF-2010  $(n,\gamma)$  reactions are split as shown in Table 6.

Table 6. Numbers of different final states in EAF-2010.

Reaction	FS = 0	FS = 1	FS = 2	Total
$(n,\gamma)$	812	230	22	<b>1064</b>

Every target leads to an FS = 0 state. Note that there are 816 targets in the EAF-2010 library, however there are no  $(n,\gamma)$  reactions for  $^3\text{H}$ ,  $^4\text{He}$ ,  $^{247}\text{Pu}$  and  $^{257}\text{Es}$ . Hence a total of 812 target isotopes in the library undergo a  $(n,\gamma)$  reaction. The  $(n,\gamma)$  cross section data are from a range of sources, and the number of reactions from each is shown in Table 7.

Table 7. The number of capture reactions from each data source in EAF-2010.

## EAF-2010 (n, $\gamma$ ) evaluation tools

Different evaluation tools and model codes have been used to generate the data that are lacking from the available major evaluated data libraries. They are: TALYS, FISPRO, MASGAM and MASGAM + SIG-ECN which are described above and in more detail in reference 54.

Several new evaluations were performed using the code NGAMMA for EAF-2001; a few of these data are still used in EAF-2010. The code NGAMMA [92] was adopted for fast calculations of (n, $\gamma$ ) cross sections in a similar way to MASGAM. Many input parameters (optical model parameters, level densities, gamma-ray strength functions) can be prepared from available global systematics or can be inputted manually using local parameters.

The non-threshold reactions (n, $\gamma$ ) and (n,f) should contain resonance data. While this is the case for important targets, many targets do not have this information. In cases where experimental resonance data exists it has been possible to add a single s-wave resonance at a suitable energy so that the correct resonance integral can be obtained. This Single Resonance Approximation (SRA) is described above (page 14); it has been applied to some reactions in EAF-2010.

## EAF-2010 actinide targets

The content of the EAF-2010 actinide sub-file includes 102 targets, ranging from  $^{211}\text{Rn}$  up to  $^{257}\text{Fm}$ . Only minor improvements have been made in this sub-file in the production of EAF-2007. There are 5,936 reactions in EAF-2010 on actinide targets compared to 5,865 in EAF-2007.

Data sources have been changed for most targets, generally to TALYS-6a or TENDL-2009. The data sources and reaction types for the actinide targets are listed in Table 8. The resulting sub-file can be claimed to be the most complete evaluated actinide data file available.

Table 8. Origin of actinide data in EAF-2010.

Data Source	Number of reactions

ENDF/B-VI.7	1
ENDF/B-VI.8	1
ENDF/B-VII.0	2
ENDF/B-VII.2	11
ESTIMATE	10
EXIFON	1
JAERI	3
JAERI(MDF)	11
JEF-2.2	22
JEF-2.2(MDF)	3

Next the data source is given, which in the above example is MASGAM. A complete list of the data origins used to build the EAF-2010 library is given in Table 4, which identifies each source library or processing code which was used to calculate the cross section. The second line repeats the data source and then appends additional text to indicate further processing of the data. Currently the possible strings are:

- ; ADD (for Mod Type = 1, 11, 12, 16)
- ; SYST (for Mod Type = 2)
- ; EXP (for Mod Type = 3)
- ; RN (for Mod Type = 4, 6)
- ; DEL (for Mod Type = 5)
- ; QVALUE (for Mod Type = 7)
- ; NUM (for Mod Type = 8)
- ; PEQ (for Mod Type = 9)
- ; INT (for Mod Type = 10)
- ; MERGE (for Mod Type = 13, 18)
- ; ADJUST (for Mod Type = 14, 15, 19)

The SAFEPAQ-II User manual [2] gives more details of the Mod Type. ADD indicates that one or more data points have been added (for example if Mod Type = 11 then a  $1/v$  addition has been carried out). SYST indicates that a renormalisation to systematics has been carried out. EXP indicates that a renormalisation to experimental data has been carried out. RN indicates that a renormalisation has been carried out (for example if Mod Type = 6 then a linearly energy dependent branching ratio has been applied). DEL indicates that data points at high energy have been deleted. QVALUE indicates that the  $Q$ -value has been altered. NUM indicates that the number of data points at low energy has been changed. PEQ indicates that the Pre-equilibrium component (the direct capture) has been added to the cross section at high energies (usually important when  $E > 1$  MeV). INT indicates that the interpolation law has been changed in an energy range. MERGE indicates that a second data source has been used at high (Mod Type = 13) or low (Mod Type = 18) energies and ADJUST means that the energy or cross section value of a data point have been adjusted.

The Quality score is a value introduced in EAF-2003 that indicates the agreement of the library data with available experimental data. Both differential and integral data are considered. The meaning of the scores is shown in Table 10.

Table 10. EAF-2010 Quality scores.

Score	Description
0	No experimental data exists
1	Limited differential data which disagrees with the library (weak disagreement)

2	Limited differential data which agrees with the library (weak agreement)
3	Differential data which disagrees with the library (strong disagreement)
4	Differential data which agrees with the library (strong agreement)
5	Both differential and integral data exist or only integral data exist and these are not in agreement with the library
5 <sub>0</sub>	Differential data are missing and unsatisfactory agreement with integral data
5 <sub>1</sub>	Unsatisfactory agreement with differential and integral data
5 <sub>2</sub>	Satisfactory agreement with differential and unsatisfactory agreement with integral data
5 <sub>3</sub>	Differential data are missing and satisfactory agreement with integral data
5 <sub>4</sub>	Unsatisfactory agreement with differential data and satisfactory agreement with integral data
6	Both differential and integral data exist and they are in agreement with the library (validation)

### EAF-2010 modifications

SAFEPAQ-II carries out a large number of modifications (and pre-modifications), most automatically (dependent on the various flags set up in the Parameter database) but some through single reaction processing. There were 36,010 modifications made in producing EAF-2010. The procedures carried out for branching are complex and are described in detail in the SAFEPAQ-II User manual [2].

Table 11. EAF-2010 modifications classes.

Reactions	Number
Pre-modifications only	2125
Modifications only	36010
Neither	28121
<b>Total</b>	<b>66256</b>

Table 11 shows that 28,121 reactions, about 40 %, remain identical to the EAF-2007 library. These represent mostly high threshold reactions for which there are no experimental data or systematics and where the data are taken from the most recent TALYS. For the majority of remaining reactions some modification has been made by SAFEPAQ-II to improve the data that exist in the various source libraries, making it more suitable for activation and transmutation related applications.

### EAF-2010 validation

EAF-2010 can be tested by the validation options in SAFEPAQ-II for consistency against the available experimental database or against

predictions from systematics. Two main validation processes can be performed; one internal where comparison is performed against the database stored in the Parameter database and the other external where EAF-2010 excitation functions are compared either with EXFOR experimental data or other evaluated data files.

The EXFOR CD-ROMs are used by SAFEPAQ-II; data are selected from these and placed in the SAFEPAQ-II database EXFOR. It is from the latter that datasets can be displayed during visualisation. Considerable efforts have been to ensure that the EXFOR data selected are both correct (daughter isomeric state and cross section units are two examples of checks) and complete. Checks have been made to ensure that all the available experimental data above 20 MeV have been selected to cover and improve the high-energy region of the library. Some recent experimental data sets are not yet present in EXFOR. To allow these data to be used for the graphical comparisons a recently introduced feature of SAFEPAQ-II was used. This allows experimental data to be entered into the Private EXFOR database, once entered these data are automatically included in the graphs along with the existing EXFOR data.

The very significant increase in the number of reactions compared to EAF-2003 or JEFF-3/1/A (factor 5) has not been matched by the increase in EXFOR available data (factor 1.04 increases in data sets, but only 1.01 increases in number of reactions). Consequently only about 2.5% of the EAF-2010 library has been visually validated by comparing the excitation function with the experimental EXFOR database over parts of their energy range. When the EXFOR validation indicated reactions which required revisions, two different ways of correcting the data have been applied:

- Replacement by a new evaluation (either from another source or a new calculation), in particular for cases with shape problems in the excitation function.
- Renormalisation of the whole or part of the excitation function through the interactive options available in SAFEPAQ-II.

The results of integral experiments have also been used to adjust data. Validation of activation code predictions, and thereby of the cross section and decay data, has been carried out by means of direct comparison with measurements of various materials under fusion-relevant neutron spectra. Having access to a variety of sources has allowed the energy dependence of the analysis to be very complete. Since the EASY-2005 validation [124] integral data became available at energies above 20 MeV. The feedbacks from this validation exercise have been used in the generation of EAF-2010. Materials samples were irradiated in a wide range of simulated D-T neutron fields at JAERI FNS, Sergiev Posad SNEG-13, FZK Isochron-

cyclotron, ENEA FNG and the Řež cyclotron, and different responses such as neutron spectra, emission spectra, kerma, activity and decay heat have been measured, allowing direct comparison with the code predictions [125,126,127,128,129,130,131,132,133,134,135,136,137,138,139,140,141,142,143,144,145,146,147,148,149,150,151,152,153,154,155,156,157,158,159,160,161,162,163,164]. All the latest integral validation reports [168,169] can be found on the EASY web site <http://www.ccfе.ac.uk/EASY.aspx>.

The results of the different validation exercises, combined with other sources of information, led to a set of corrective actions to be carried out on some important reactions. These have been implemented in EAF-2010, and include cross section renormalisation, shape correction in a given energy range, threshold and  $Q$ -value correction, partial cross section adjustment and some new energy-dependent isomeric branching ratios. The fact that these benchmarks were performed by several research institutions using different activation codes and decay data has allowed clarification of the reasons for many discrepancies. These have been found to be partly due to inaccurate decay data, partly to inaccurate cross section data, and partly to a variety of inadequate calculational processes.

### ***Experimental validation – C/E***

The experimental data available for selected cross section channels at three energy ranges, 14.5 MeV, 30 keV (for (n, $\gamma$ ) reactions) and 0.0253 eV held in the Parameter tables can be compared with the values in Final leading to the corresponding C/E values (C refers to the library value and E to the experimental data). These are plotted for the various reaction channels. This process is an interactive one, thus the data in the file have been corrected using feedback from the early comparisons. This method presents clear advantages: criteria can be set to decide when to apply a renormalisation process and detailed inspection indicates deficiencies that can be traced to either the raw data or to their treatment in SAFEPAQ-II.

The (n, $\gamma$ ) experimental validation results are presented separately due to their importance and specificity. Such comparisons are made at thermal energy, 30 keV and at about 14.5 MeV and are based on a compilation of many references [10,36,47,49,59,165,166,167]. An ideal C/E ratio would clearly be 1, but in practice there is a distribution of C/E about this value. The number of C/E ratios available (the individual experimental results are flagged to show if they are to be used for validation) for testing EAF-2010.

Another validation tool, traditionally used in the EAF project, is the comparison of cross section values at a distinct energy (usually with neutron energies around 14 MeV) with the corresponding selected (recommended) experimental cross section. This comparison is

represented by a C/E ratio. The database of such entries has been generated and stored in the parameter.mdb of SAFEPAQ-II code [2], which is continuously updated with new measurements. However, for reaction channels with the threshold values closed to 14 MeV the comparison constitutes a large uncertainty because the cross section energy lies in a steep raising part of the excitation curve and should be used with a special attention and care. The same approach can also be applied with the cross section systematic at 14.5 MeV, in detail described again in [2]. C/S gives either additional information for special individual cases, where C/E is sometimes in contradiction or can be used as general information of the trend, complementary to the SACS results. In all C/E histograms discussed here are the data outside  $0.5 < C/E < 2$  uncertainty margin been individually examined.

### (n,2n) reaction

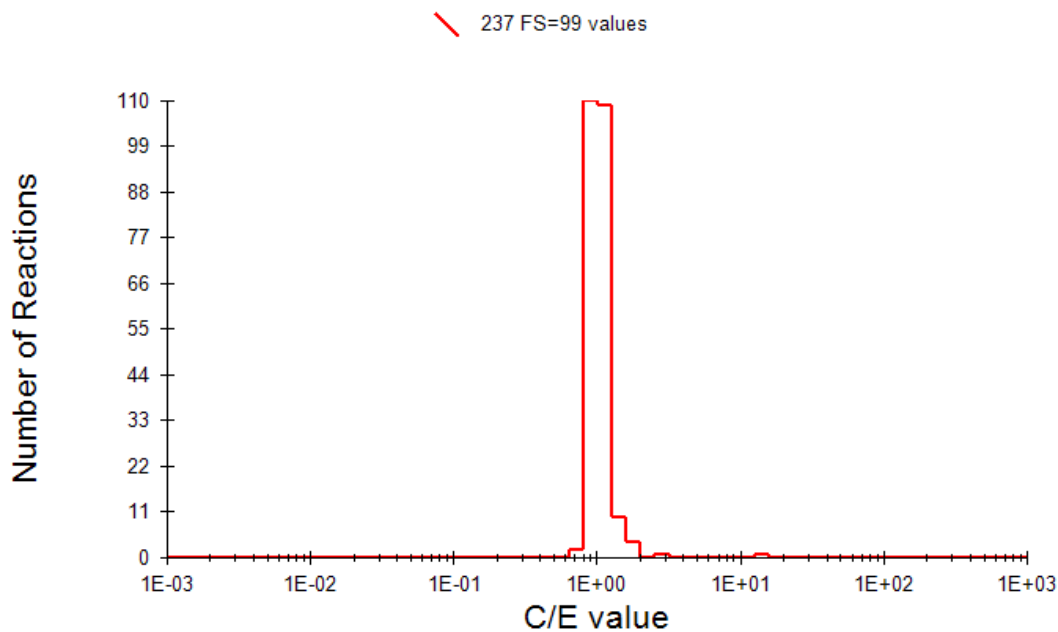

Figure 2. C/E plot for 14.5 MeV experimental data (n,2n) reactions

This C/E histogram demonstrates a consistent behaviour of the 14.5 MeV (n,2n) cross sections for which we can conclude that a very good agreement with experimental measurement exist.

**(n,3n) reaction**

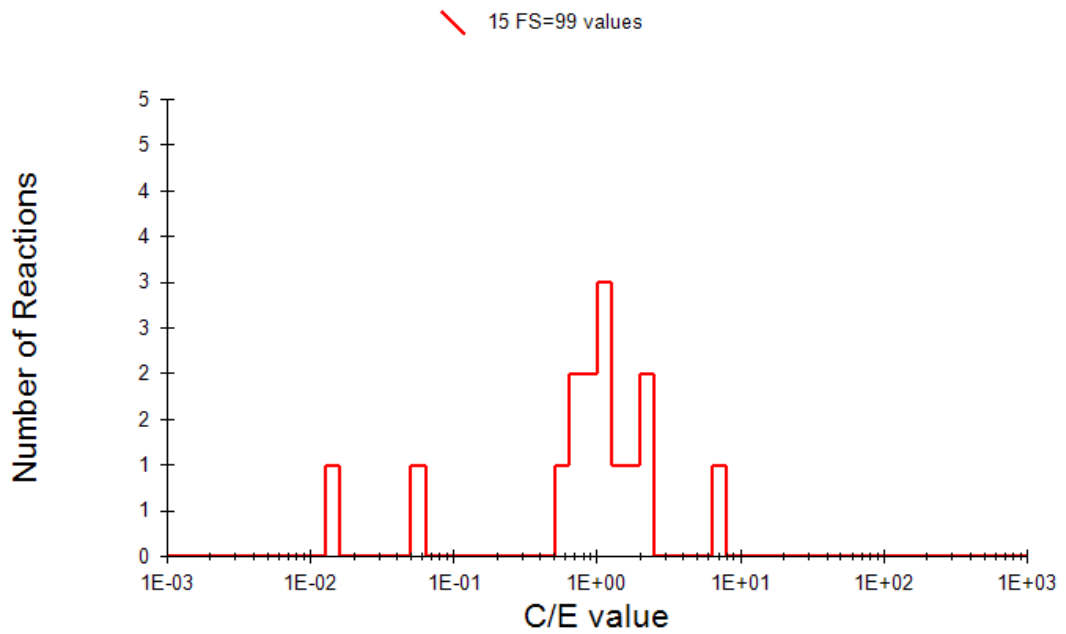

Figure 3. C/E plot for 14.5 MeV experimental data (n,3n) reactions

The outlier exemplify a rather poor experimental energy characterization, usually very close to the reaction threshold that induce large and questionable C/E values.

**(n,n'p) reaction**

Figure 4. C/E plot for 14.5 MeV experimental data (n,n'p) reactions

This reaction channel C/E show an excellent agreement, no outlying data. However, only a limited number of experimental data (only charge particle detection have been used, no activation data) are considered.

**(n,n' $\alpha$ ) reaction**

Figure 5. C/E plot for 14.5 MeV experimental data (n,n' $\alpha$ ) reactions.

The majority of the experimental data are considered to close to the reaction threshold and so have a limited impact for validation purposes

**(n,p) reaction**

Figure 6. C/E plot for 14.5 MeV experimental data (n,p) reactions

All C/E around 14.5 MeV are in a good agreement and close to unity, a small number of disagreements came either from unreliable (old) measurements, some of them close to the threshold energy.

Figure 7. C/E plot for 0.0253 eV experimental data (n,p) reactions

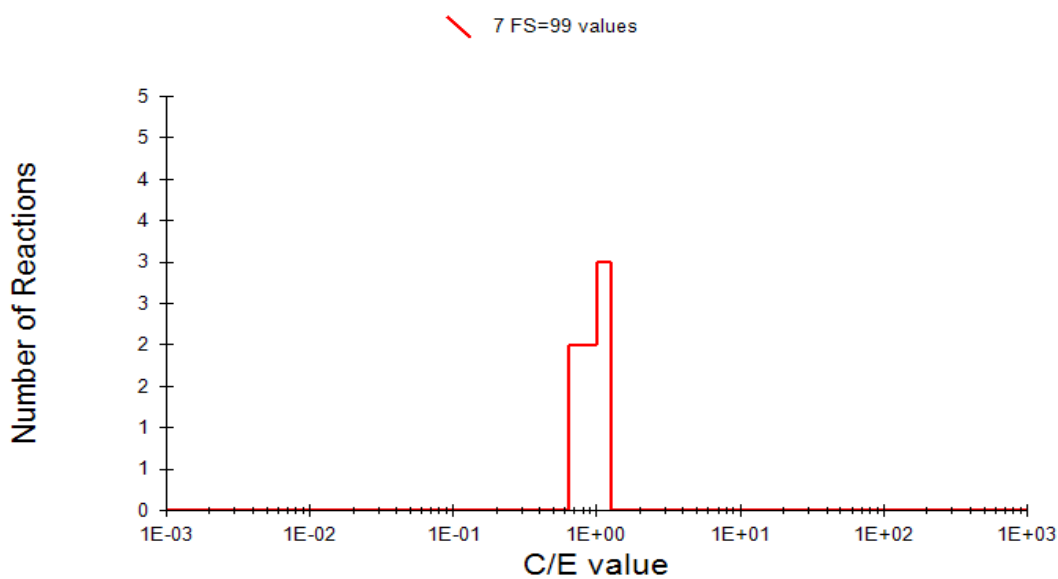

Figure 8. C/E plot for resonance integral experimental data (n,p) reactions

For the thermal cross sections and resonance integral C/E, all data are considered as in good agreement, that is assuming  $0.5 < C/E < 2$  uncertainty margin.

**(n,d) reaction**

Figure 9. C/E plot for 14.5 MeV experimental data (n,d) reactions.

The limited amount (30) of experimental data (only charge particle measurements have been considered) gives a reasonable agreement, with 7 outlying cases. However, the better test is the analysis of the summed (n,d + n,n'p) cross section, which lead to a much better comparisons than the results per reaction.

**(n,t) reaction**

Figure 10. C/E plot for 14.5 MeV experimental data (n,t) reactions

All outlying reactions have the experimental data point too close to the threshold energy to bear any significance, and no renormalisation are advisable.

**(n,h) reaction**

There are no reliable experimental data, all cross section data can be considered as upper limits. The reason for this situation is two fold, the data are usually measured at energies around 14 MeV close to the reaction threshold where the cross section values are very small. Second, the measurement of such small cross sections is complicated by the competition of other reaction channels from the elemental and/or isotopic impurities, which mask the real (n,h) cross section. Further complications derive from the energy shift of calculated excitation curves and the small millibarn expected values. All this seems to indicate some inconsistencies in the Optical Model parameters. More studies are needed to clarify this situation along side more and better experimental data.

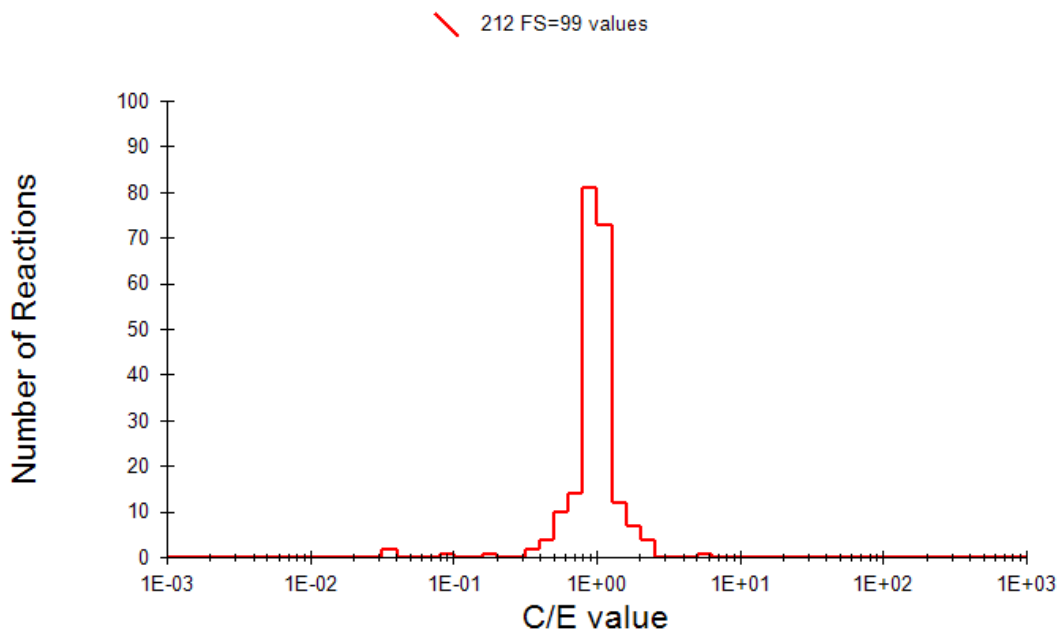

**(n, $\alpha$ ) reaction**

Figure 11. C/E plot for 14.5 MeV experimental data (n, $\alpha$ ) reactions

The (n, $\alpha$ ) reactions are in a good agreement with both experimental and systematic predictions at 14.5 MeV. The small Gaussian deviating data can be explained by the scatter of the experimental information has the energies are too close to reaction threshold.

In addition very satisfactory results are obtained for non-threshold (n, $\alpha$ ) reactions, as demonstrated by the two following figures.

Figure 12. C/E plot for 0.0253 eV experimental data (n,α) reactions.

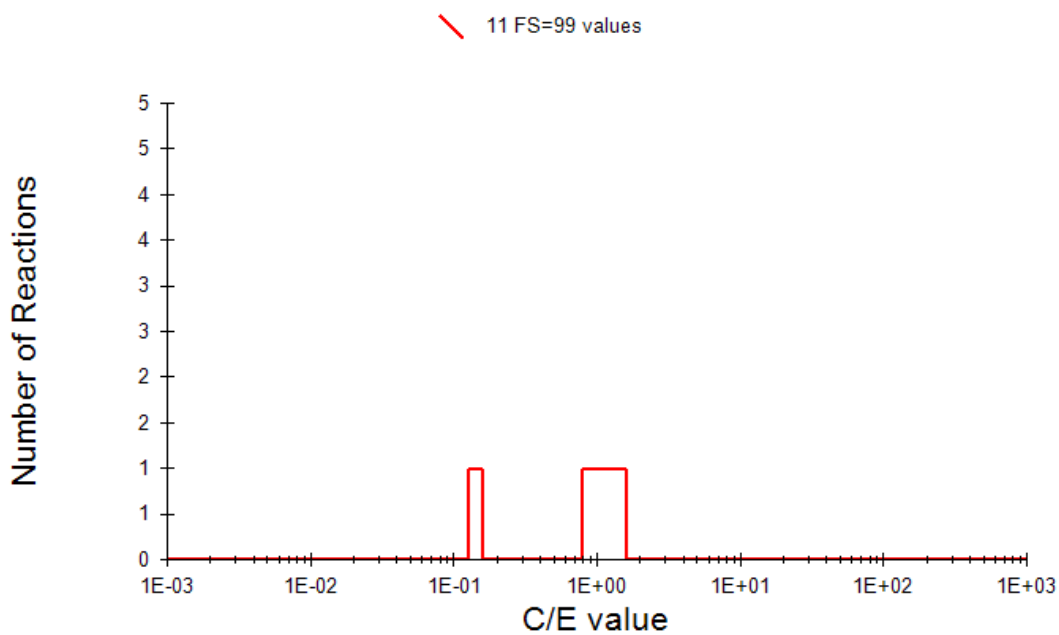

Figure 13. C/E plot for resonance integral experimental data (n,α) reactions

(n, $\gamma$ ) reaction

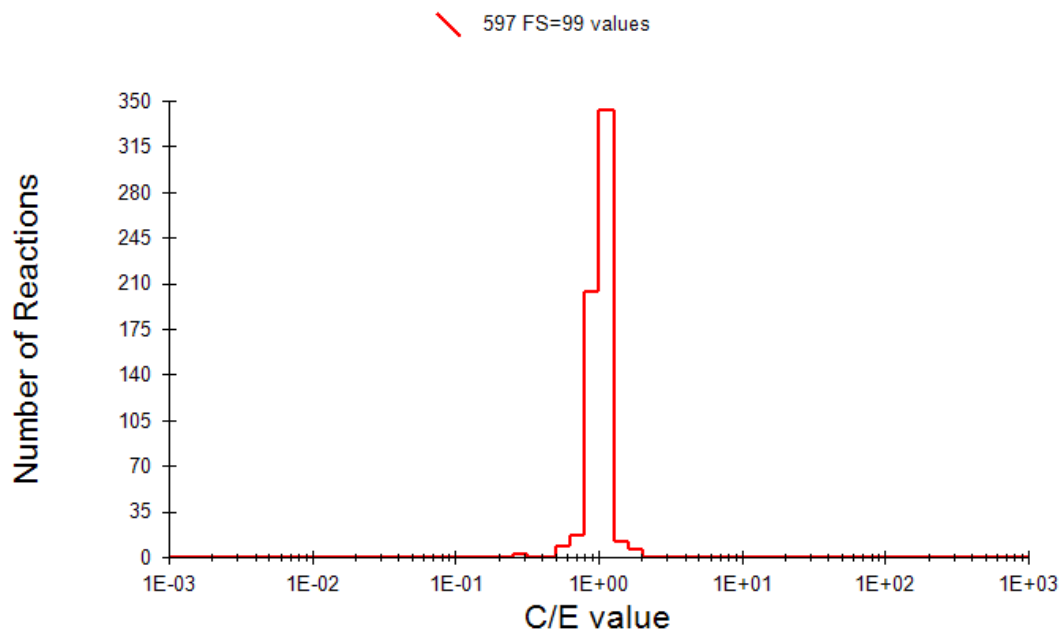

Figure 14. C/E plot for 0.0253 eV experimental data (n, $\gamma$ ) reactions

Figure 15. C/E plot for 30 keV experimental data (n, $\gamma$ ) reactions

Figure 16. C/E plot for resonance integral experimental data (n,γ) reactions.

Figure 17. C/E plot for 14.5 MeV experimental data (n,γ) reactions.

The Thermal cross sections deviate only for two reactions from a 50% uncertainty margin, namely  $^{86}\text{Kr}(n,\gamma)$  and  $^{92}\text{Mo}(n,\gamma)$  with C/E = 0.29 and 0.26, respectively. For  $^{86}\text{Kr}(n,\gamma)$  the recent ENDF/B-VII evaluation has been adopted, which is in the thermal region reasonably close to the  $1/v$  component. Since the new resonance parameters form the basis of the low energy point-wise data, this evaluation has been adopted without any modification. The second reaction is the  $^{92}\text{Mo}$  capture for which the same type of explanation

exists, the ENDF/B-VII evaluation fits another recommended experimental  $\sigma_{th}$  value.

All other histograms (at  $E_n = 30$  keV, 14.5 MeV and RI) are discussed in detail in [171] with explanations for outlying C/E values.

### (n,f) reaction

Figure 18. C/E plot for 0.0253 eV experimental data (n,f) reactions

Figure 19. C/E plot for resonance integral experimental data (n,f) reactions.

All thermal and  $1/v$  components of the (n,f) reactions are in a good agreement with the experimental data and their uncertainty and deviation. More problems exist in the C/E for resonance integrals, where few but noticeable deviations occur, however, some Resonance Integral measurements seems very uncertain and questionable.

### Resonance Integral

Another very important experimental validation process can be carried out on the resonance integrals of certain reaction channels. To calculate the resonance integral the EAF-2010 data (which are Doppler broadened to 294 K) are integrated from 0.5 eV to 100 keV. Such a validation allows a clear assessment of the quality of the cross sections profile over a wide energy range. The experimental data base combines both real experimental data with resonance integrals derived from measured resonance parameters. Figure 20 shows the C/E distribution for resonance integrals for all the resonant reactions (n, $\gamma$ ), (n,p), (n, $\alpha$ ) and (n,f).

There have been some updates in the resonance data for all the reactions, and this reflects the slight improvement in the C/E plot in EAF-2010 compared to the earlier EAF-2007.

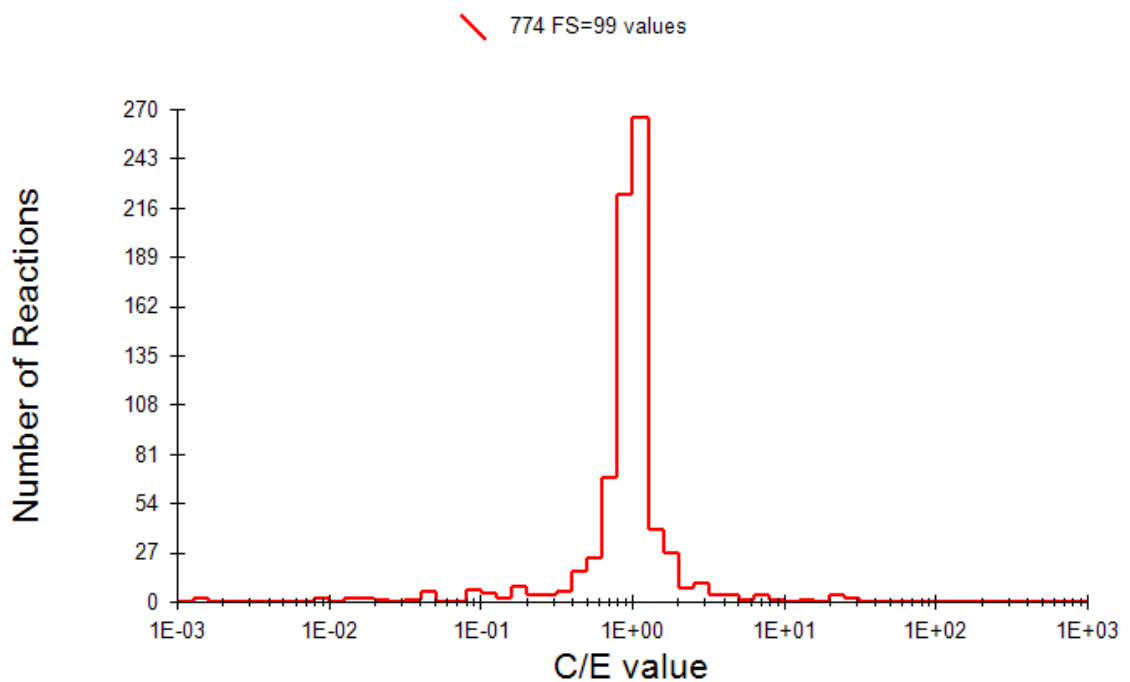

Figure 20. C/E distribution of resonance integrals in EAF-2010.

## Summary of C/E analysis

The results of the C/E histograms analysis show that the majority of the tested EAF-2010 point-wise data are in a good agreement with experimental differential cross sections at  $E_n=0.0253$  eV, 30 keV (for capture reaction) and at 14.5 MeV. The deviating C/E values have been tabulated and discussed and for many, improvements have been found. This has often been done by selecting more recent updated EXFOR entries as recommended experimental cross section values. In addition, the experimental resonance integral values have been used for the C/E analysis for the (n, $\gamma$ ), (n,p), (n, $\alpha$ ) and (n,f) reactions.

The differential validation of the EAF-2010 point-wise data has been completed. It consists of a detailed comparison of all reactions, supported with the experimental data (Score 1–6 reactions), with EXFOR and other experimental data. This information has been used in choosing the best excitation curve (either calculated or evaluated) as the data source in the master database.

## Systematic validation – C/S

The predictions from systematics available for selected cross section channels at 14.5 and 20 MeV can be compared with the values contained in the library leading to corresponding C/S values (C refers to the library value and S to the systematics prediction). Figures 21 to 37 present the results of the comparison for EAF-2010. The same analysis of the individual reaction channels that was carried out for the experimental validation can be applied here. Comparison with systematic predictions can be carried out for many channels. However, certain limitations do apply: the energy is limited to 14.5 and 20 MeV, with the exception of 30 keV information for each capture channel, and only total cross section C/S values can be compared. The validity of the formulae used may not cover the complete mass range and systematic formulae do not always account for competing reactions.

This single-energy feature of systematic predictions indicates that if one wants to use the C/S validation, say for renormalisation, then one has to proceed with caution. This information can evidently be used as additional information in individual cases. However, it makes its general implementation, as proposed and partially used earlier, very difficult.

From Figure 21, where all the C/S values are presented, one can immediately notice the broad coverage, with 35% of the reactions with data at 14.5 MeV compared. This in itself is quite an achievement and tends to demonstrate the rather satisfactory behaviour of the systematic formulae. It is important to keep in mind

here that the same data, but in lesser number, have been previously compared with experimental information.

Figure 24 shows the C/S values for the (n,d) reaction at 14.5 MeV. It is important to note that the peak of the histogram is now centred around unity rather than the value of 10 found for EAF-2005. This improvement in the predictive power of TALYS is partly due to active feedback of this problem to the code authors.

A similar remark applies to the (n,t) histogram shown in Figure 28. However, for (n,2n), (n, $\alpha$ ) and (n,p) the histograms (Figure 22, 23 and 26) show only a slight improvement over EAF-2007.

Figure 29 and 30 representing the C/S values for the (n,n' $\alpha$ ), and (n,n'p) reactions, clearly demonstrate the difficulties encountered in applying systematic formulae for these reactions. One of the reasons for the broad C/S distribution is the even/odd effect which is not considered in the systematics. Differences of about an order of magnitude can commonly be spotted that highlight less than satisfactory library contents. However, those are not major reactions and it has been shown by inventory calculations that they are of importance only in a small number of particular cases.

Figure 33 to 37 illustrate the C/S histograms for data at 20 MeV, and while in all cases the peak is reasonably sharp it should also be noted that in all cases the peak is centred slightly above unity. This is particularly evident in the (n,t) and (n,n'p) reactions.

At this stage it is important to keep in mind that even if certain cross sections are known to high accuracy within a particular energy range then it is not uncommon to find discrepancies at energies outside this range when comparing data in evaluated files, experimental values or systematic information.

A comparison can be made at 14.5 MeV against (n, $\gamma$ ) systematics. At this energy systematic formulae can be applied with some success, which is fortunate in view of the lack of data sources that exist in the experimental database. Figure 34 clearly demonstrates that when a histogram of C/S values is plotted for all the 812 (n, $\gamma$ ) total cross sections, 80% of the data are within the range 0.8 - 1.25. The second peak at around 2 to 3 on the abscissa present in EAF-2007, (~90 reactions), has been removed. These ratios originated from older evaluations, which are generally of reasonable quality, except in the pre-equilibrium range, where an approximate treatment was applied. These data sources have been replaced or PEQ correction applied. The small number of reactions with very small values of C/S are all for very low mass targets for which the systematics are not applicable. Figure 35 shows C/S values for the (n, $\gamma$ ) reaction at 30 keV. A rather

good agreement, centred around unity, is obtained after correcting the basic formula, as discussed in detail in [172].

## SACS validation

Standard quantities investigated in the SACS method [173] are  $\sigma_{\max}$ ,  $E_{\max}$ , the full width at half maximum (FWHM),  $\Delta$ , and a recently added parameter called skewness,  $k$ , defined as  $k = (\Delta_R - \Delta_L) / \Delta$ . Where  $\Delta_R$  and  $\Delta_L$  are left- and right widths at half maximum from the  $E_{\max}$  energy point, respectively, such that their sum equals  $\Delta$ . For the majority of reactions  $A < 20$  data and actinide targets are not considered. The reason is that for low- $A$  targets the reaction mechanism is often of a non-statistical character, which may result in a strong influence on the behaviour of the shape and magnitude of the excitation curve. Further the actinide targets are omitted, where the competition of fission with all the particle emission channels strongly influences the magnitude of cross sections, which thus may again cause a deviation from the trend.

### (n,2n) reaction

The (n,2n) cross section data have been corrected for competing (n,n'p) cross sections for  $s \leq 0.1$ . The eye guiding trends are also plotted in order to demonstrate the smooth trend of SACS parameters as a function of asymmetry. The omitted targets, if any, are also given in the plots, below the heading.

Figure 38. (n,2n) + (n,n'p) SACS plot: maximum cross section versus asymmetry. Actinides and A<20 data points are excluded.

Figure 39. (n,2n) SACS plot: energy at maximum cross section versus asymmetry. Actinides and A<20 data points are excluded.

Figure 40. (n,2n) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded. Deviating points below  $s = 0.05$  are neutron deficient targets  $^{21}\text{Ne}$ ,  $^{45}\text{Ti}$ ,  $^{50}\text{Cr}$ ,  $^{52}\text{Mn}$ ,  $^{54}\text{Fe}$ ,  $^{57}\text{Ni}$ ,  $^{56}\text{Co}$  and  $^{68}\text{Ge}$ .

Figure 41 (n,2n) SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded

It can be concluded that the (n,2n) data are in a good agreement with the expected smooth behaviour of studied SACS quantities. The deviating data belong to neutron deficient targets that are away from

the stability line, where probably the global input parameters do not properly describe the neutron emission.

In the actinides range mass region the (n,2n) and (n,f) channels are the two dominating reactions of the inelastic cross section below 20 MeV. Their sum is slowly increasing with  $A$  and the asymmetry  $s$ , similarly to the  $\sigma$  inelastic increase. In two following plots the  $\sigma_{n,2n} + \sigma_f$  value for EAF-2007 and EAF-2010 have been plotted. The improvement in EAF-2010 is visible for data points with  $s > 0.20$ , with much a more smooth data distribution. This has been achieved by individual corrections applied to  $\sigma_{\max}$  of (n,2n) reaction bearing in mind large  $\sigma_f$  uncertainty for minor actinides. The larger scatter for targets with  $s < 0.1$  is due to (n,n'p) competition, which in these plots has not been corrected for.

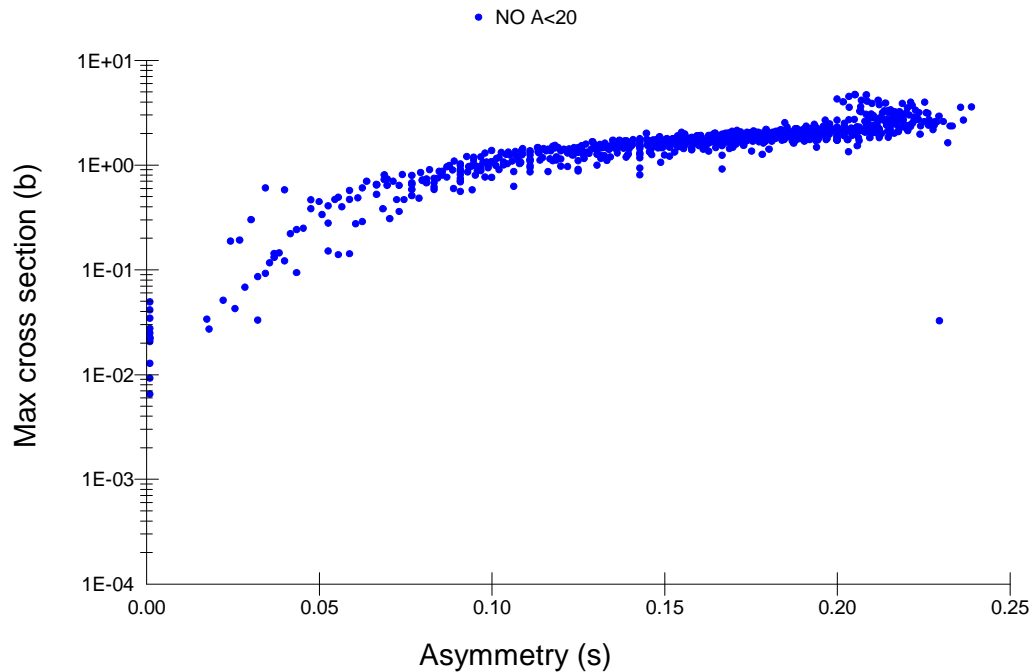

Figure 42. (n,2n) + (n,f) SACS plot using EAF-2007 data: maximum cross section versus asymmetry.  $A < 20$  data points are excluded

Figure 43. (n,2n) + (n,f) SACS plot using EAF-2010 data: maximum cross section versus asymmetry.  $A < 20$  data points are excluded.

#### (n,3n) reaction

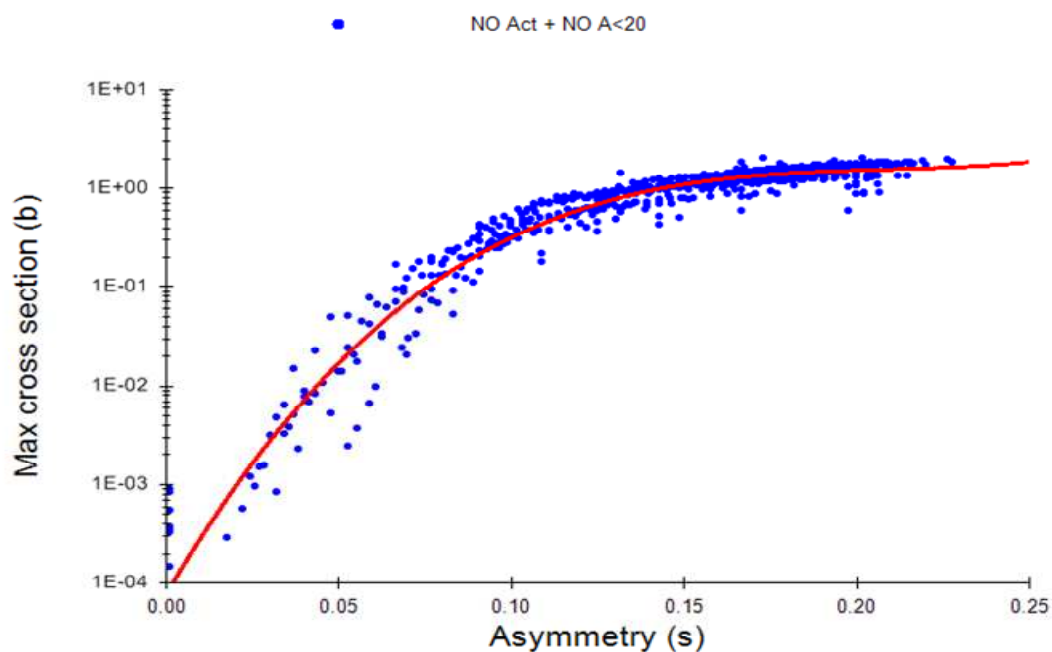

Figure 44. (n,3n) SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Figure 45. (n,3n) SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The deviating points close to  $E_{\max} = 60$  MeV belong to neutron deficient targets, where apparently a large uncertainty exist in all neutron emission data, as an example the  $^{62}\text{Zn}$  data can be mentioned ( $s = 0.03$ ). The other outlying point at  $s = 0.1$  belongs to  $^{93\text{m}}\text{Mo}$ .

Model (TALYS) calculations can lead to significant differences in profile and this is mainly due to differences in the input parameters used, in particular the level densities. However, the (n,3n) modelled data remain unaffected.

Figure 46. (n,3n) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Figure 47. (n,3n) SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The majority of targets with asymmetries  $s < 0.1$  are mainly neutron deficient targets, where the emission of 4 neutrons is very weak, and the (n,3n) reaction often dominates the neutron emission above the (n,2n) range and up to 60 MeV. This explains the broadening of  $\Delta$

and the negative skewness values, explained by the fact that the excitation curve exceeds the 60 MeV energy limit.

**(n,p) reaction**

Figure 48. (n,p) SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Figure 49. (n,p) SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Points with  $E_{\max}$  close to zero belong to non-threshold reactions with a large estimated cross section from TALYS calculation, based on the assumption of  $\sigma(n,\gamma)/\sigma(n,p)=\text{const}$  at low energies [170].

Figure 50. (n,p) SACS plot: width at half-maximum cross section versus asymmetry.

The outlying point above  $s = 0.2$  belongs to isomeric target  $^{194m}\text{Ir}$ .  
The step-wise shape of the curve is discussed in detail in [173,174].

Figure 51. (n,p) SACS plot: skewness parameter versus asymmetry.  $A < 20$  data points are excluded.

The skewness parameter should be close to  $k = 0$  for targets with  $s < 0.1$ , based on FWHM behaviour. This is nicely shown in the last figure for Score  $> 0$  targets, three outlying points at  $s = 0$  belong to

$^{22}\text{Na}$ ,  $^{28}\text{Si}$  and  $^{28}\text{Al}$  targets, while the other two below  $s = 0.1$  are  $^{37}\text{Ar}$  and  $^{76}\text{Br}$ . All of them are threshold reactions with a similar shape as  $^{86}\text{Y}(n,p)$  above and thus the shape deviates from an asymmetric bell form. The other outlying data point belongs to  $^{28}\text{Si}$  and has a pronounced low-energy resonance structure.

For the (n,p) reaction the data can be considered as in a good shape, However, a strong competition exists between neutron emission (n,2n) and (n,n'p) and (n,p) channels for targets with a neutron deficiency and asymmetries  $< 0.1$ .

### (n,n'p) reaction

Figure 52. (n,n'p) SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The experimentally observed dominant  $\sigma(n,n'p)$  (with cross section values close to 1b [171]) for targets with  $S(n) > S(p)$  and  $|Q_{n,n'p}| < |Q_{n,2n}|$  and  $s < 0.1$  is nicely demonstrated in the SACS data as step in  $\sigma_{\max}$  for targets with  $s < 0.1$ .

Figure 53. (n,n'p) SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The number of points with  $E_{\max}$  close to 10 MeV with  $0.05 < s < 0.13$  belong to targets from the transitional region in which the competition between (n,p) and (n,n'p) takes place and the FWHM of these reaction is changing from narrow to broad [174]. The possible uncertainty of the input parameters may be also the reason of this deviation.

Figure 54. (n,n'p) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The step-like trend of the excitation curve width, similar to (n,p), verifies the observed competition of these two reactions for targets with asymmetries below 0.1. The strongly deviating point at about  $s = 0.12$  belongs to  $^{89}\text{Y}$  for which some strange profiles are exemplified in model but also evaluated data files.

Figure 55. (n,n'p) SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded. The two deviating points at the end of the data belong to  $^{200}\text{Pt}$  and  $^{202}\text{Pt}$  targets.

For the (n,n'p) cross sections that follows a step-like behaviour for targets left from the stability line, with asymmetries  $< 0.1$ , where the competition between the neutron (n,2n) emission and the proton emission is strong more theoretical works are needed along side some experimental effort.

(n,d) reaction

Figure 56. (n,d) SACS plot: maximum cross section versus asymmetry.  $A < 20$  data points are excluded.

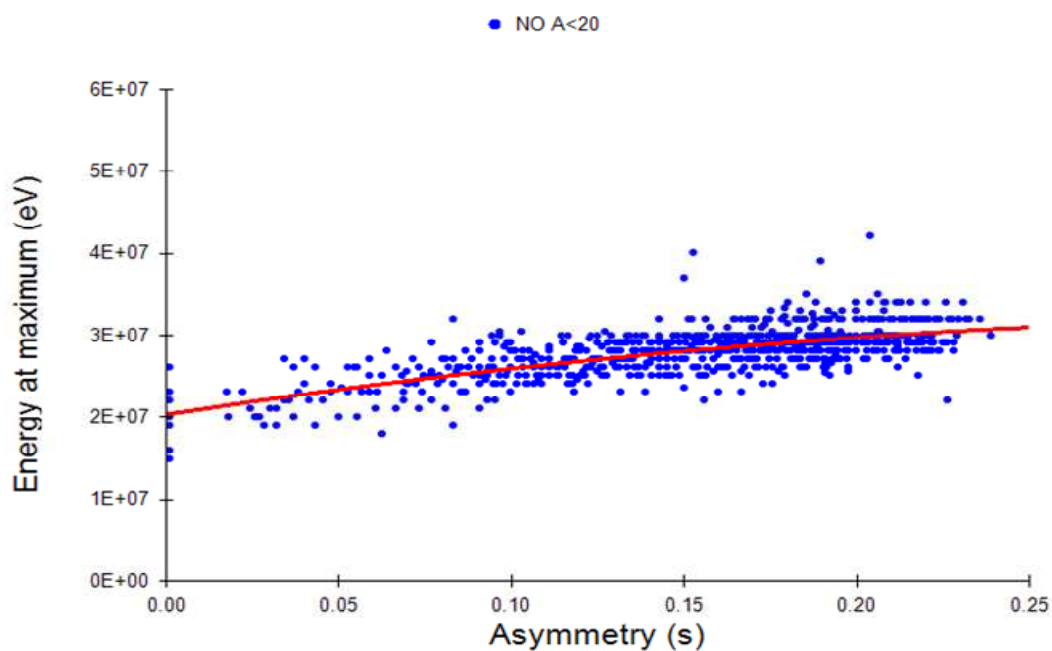

Figure 57. (n,d) SACS plot: energy at maximum cross section versus asymmetry.  $A < 20$  data points are excluded.

Figure 58. (n,d) SACS plot: width at half-maximum cross versus section asymmetry.  $A < 20$  data points are excluded

Figure 59. (n,d) SACS plot: skewness parameter versus asymmetry.

With only a few deviating points above  $s = 0.15$ , the (n,d) data demonstrates a rather uniform behaviour and a rather smooth trends on a wide asymmetry range.

**(n,t) and (n,h) reactions**

The (n,t) and (n,h) reactions belong to charge-particle emission reactions with threshold close to 14.5 MeV and thus where the experimental information is rather scarce and often not reliable, mostly due to very small cross sections. However, it seems that the situation with the (n,t) reactions, based on available EXFOR experimental data is rather sound and the predicted modelled data rather uniform. Concerning the (n,h) reactions some inconsistency have been noted particularly near the threshold.

Figure 60. (n,t) SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Figure 61. (n,t) SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A<20$  data points are excluded.

The strongly deviating point above  $s = 2.0$  belongs to the high-energy second isomer target of  $^{194n}\text{Ir}$ , for which obviously the input parameters are not realistic. The lowest point at  $s = 0$  belong to  $^{22}\text{Na}$ , where some nonstatistical behaviour cannot be ruled out.

Figure 62. (n,t) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A<20$  data points are excluded.

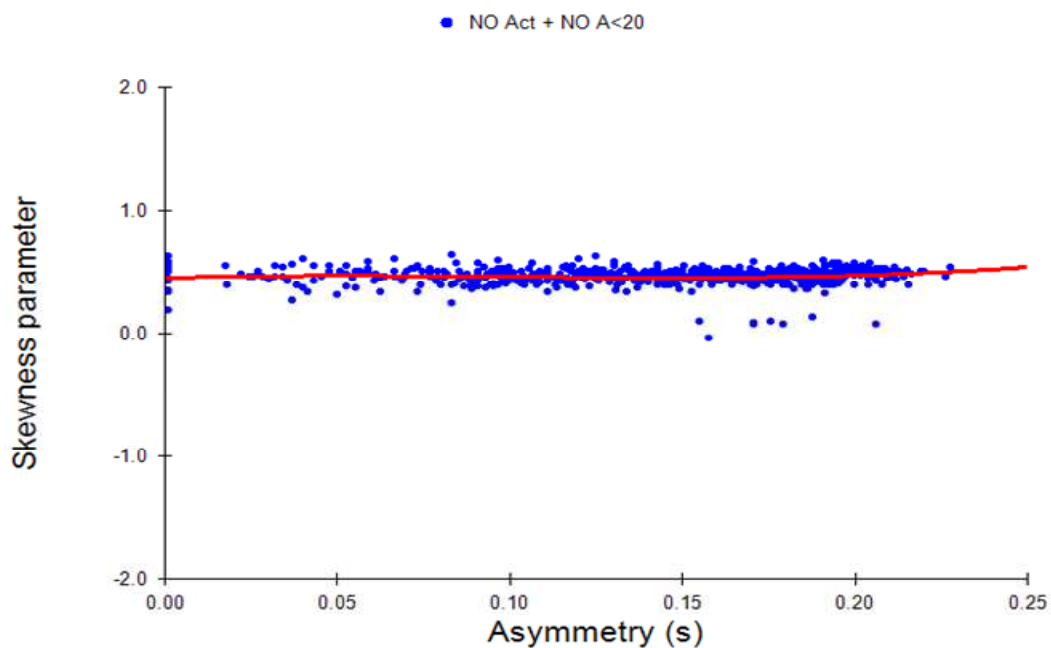

Figure 63. (n,t) SACS plot: skewness parameter versus asymmetry. Actinides and  $A<20$  data points are excluded.

Figure 64. (n,h) SACS plot: maximum cross section versus asymmetry.  $A<20$  data points are excluded.

Figure 65. (n,h) SACS plot: energy at maximum cross section versus asymmetry.  $A < 20$  data points are excluded.

Figure 66. (n,h) SACS plot: width at half-maximum cross section versus asymmetry.  $A < 20$  data points are excluded.

Figure 67. (n,h) SACS plot: skewness parameter versus asymmetry.

### (n, $\alpha$ ) reaction

Figure 68. (n, $\alpha$ ) SACS plot: maximum cross section versus asymmetry. Actinides and A<20 data points are excluded

Figure 69. (n,α) SACS plot: energy at maximum cross section versus asymmetry. Actinides and A<20 data points are excluded.

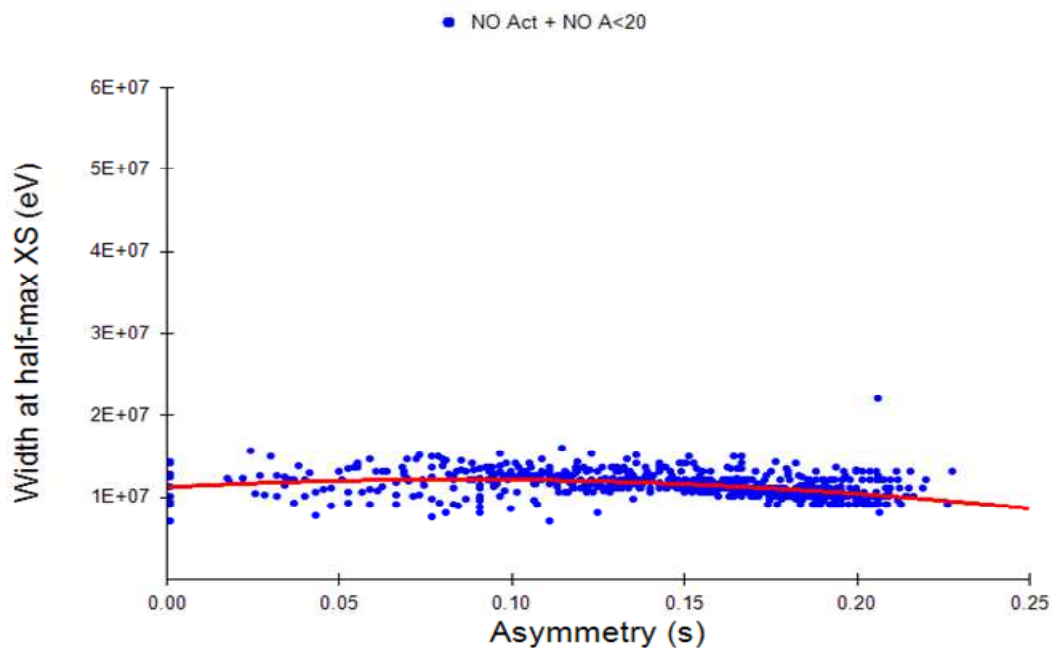

Figure 70. (n,α) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and A<20 data points are excluded.

The isomeric target <sup>194m</sup>Ir is again well above the trend line.

Figure 71.  $(n, \alpha)$  SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded.

A very consistent behaviour of all SACS parameters is usually observed for the  $(n, \alpha)$  channel.

### $(n, n' \alpha)$ reaction

Figure 72.  $(n, n' \alpha)$  SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded

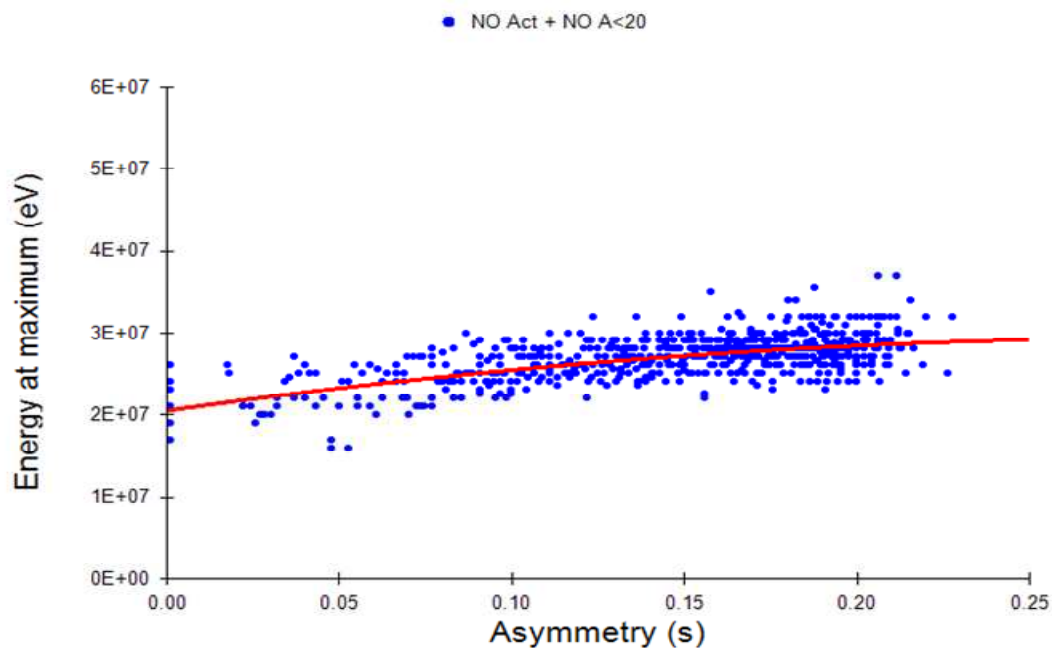

Figure 73.  $(n,n'\alpha)$  SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A<20$  data points are excluded.

Figure 74.  $(n,n'\alpha)$  SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A<20$  data points are excluded.

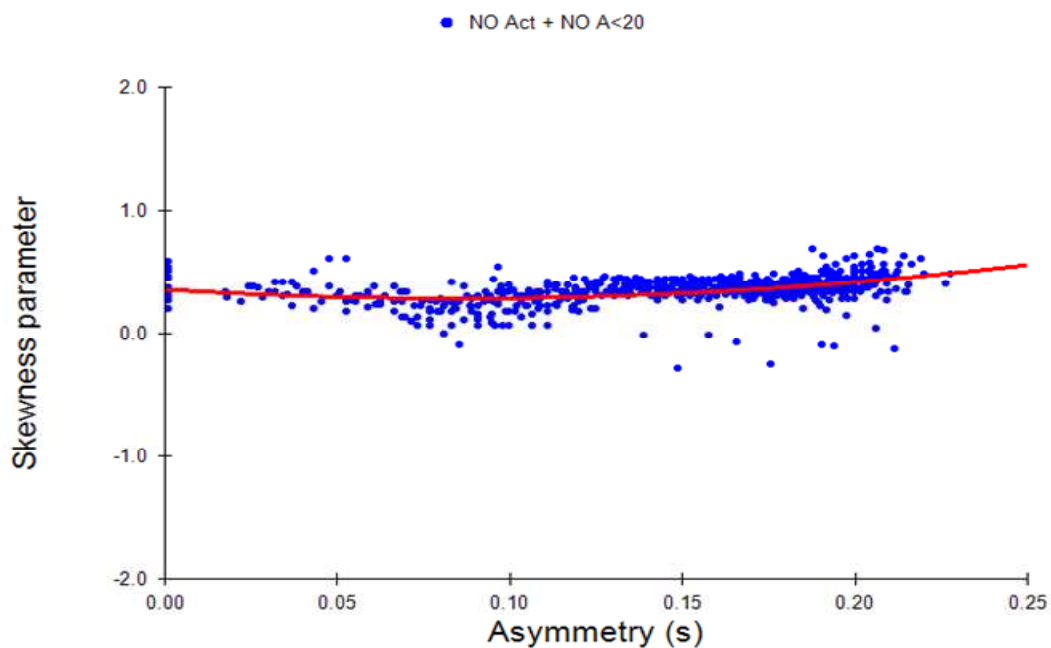

Figure 75.  $(n,n'\alpha)$  SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded

The obtained trend dependence of SACS parameters is rather satisfactory, small deviations of the  $\Delta$  and skewness parameters have been observed for seven Score = 0 targets. No modifications for these reactions are needed.

**(n,2p) reaction**

Figure 76. (n,2p) SACS plot: maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

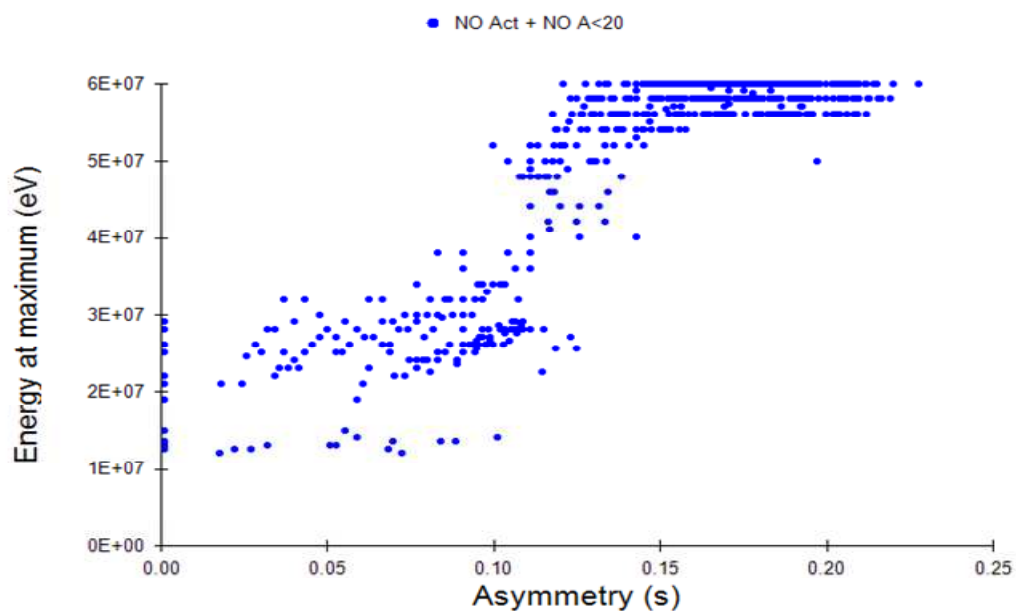

Figure 77. (n,2p) SACS plot: energy at maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded.

Figure 78. (n,2p) SACS plot: width at half-maximum cross section versus asymmetry. Actinides and  $A < 20$  data points are excluded

Figure 79. (n,2p) SACS plot: skewness parameter versus asymmetry. Actinides and  $A < 20$  data points are excluded.

The (n,2p) reaction SACS parameter exhibit two rather distinct regions, demonstrated by a steplike behaviour of  $E_{\max}$ ,  $\Delta_{1/2}$  and the skewness parameters. The first region belongs to targets with

asymmetries smaller  $< 0.15$  where the threshold is at lower energies and the emission of two protons enters the competition with other proton emission channels, such as  $(n,p)$  and  $(n,n'p)$ . For  $s > 0.15$  targets increases the threshold rapidly and only the low energy part of the bell shaped excitation function lies below 60 MeV. The EXFOR data are rather uncertain (complication with impurities) and thus the data rely only on calculations.

### $(n,\gamma)$ reaction at $E_n = 14.5$ MeV

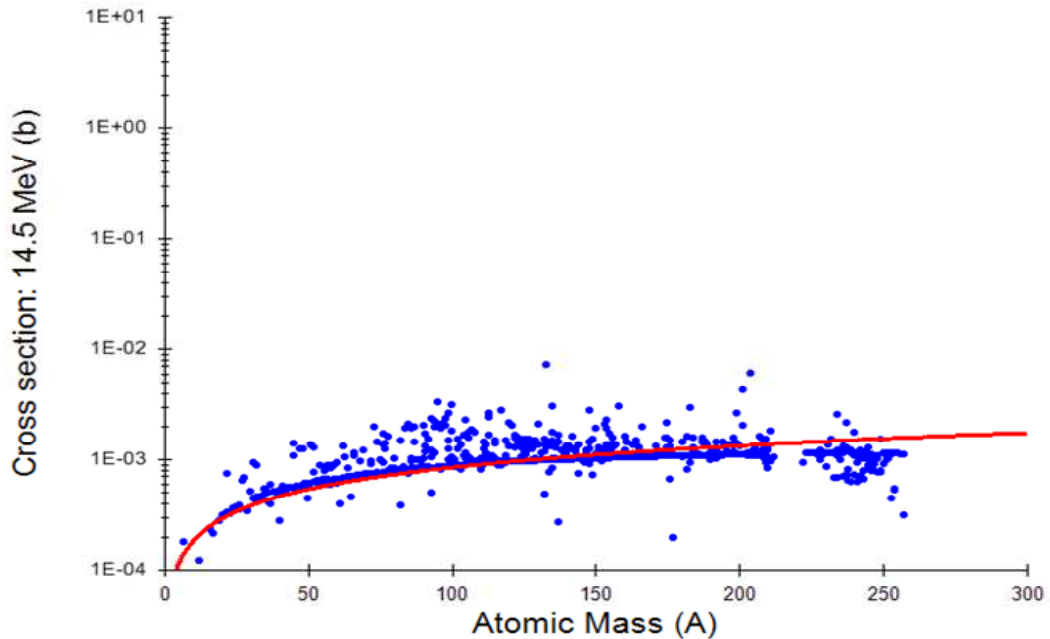

Figure 80.  $(n,\gamma)$  SACS plot: cross section at 14.5 MeV versus Atomic Mass.

For capture data, a particularly relevant validation is the cross section around 14.5 MeV, where the compound nucleus component is almost negligible and the pre-equilibrium process is dominant. The well established systematic in [2] predicts  $\sigma(n,\gamma)$  at 14.5 MeV to be around 1 millibarn with a slightly increasing dependence on  $A$ . The figure above shows the cross section as a function of  $A$  and reveals only a few outlying values from the general trend. The three most outlying points above the trend belong to  $^{133}\text{Cs}$ ,  $^{201}\text{Pb}$  and  $^{204}\text{Bi}$  targets, while those below the trend curve are  $^{137}\text{Cs}$ ,  $^{177\text{m}}\text{Lu}$  and actinide  $^{253}\text{Cf}$ ,  $^{254}\text{Es}$  and  $^{257}\text{Es}$  targets. This result confirms the usefulness and effectiveness of the capture data revision from [169] for cross sections with  $|C/S| > 2$ .

### SACS validation summary

The results of the SACS analysis proved that the majority of EAF-2010 point-wise data are satisfactory and follow the smooth trend

dependence of SACS parameters. These features are very important and support our trust in the profile of the calculated excitation curves.

The outlying data points (the vast majority of them are for data with a quality score which has been set to 0) often belong to nuclides with a large neutron deficiency, i.e. far from the stability line, for which the input parameters used in TALYS calculations may still need some further improvements. Therefore, actions to revise and study how the nuclear reaction modelling input parameters change will be considered for the future.

The results for targets with small asymmetries  $s < 0.1$  (which are also neutron deficient targets) show that the competition between the neutron and proton emission channels is strong. The behaviour of EAF-2010 data indicates that, in general, this competition is globally taken care of both in the model calculations and in evaluations. However, some particular target and reactions can be impacted by the quality of the global input parameters. This is especially noticeable for the high-energy range of the (n,p) excitation curve that carries a high degree of uncertainty.

## EAF-2010 uncertainty file

A complete uncertainty file is generated by SAFEPAQ-II for the EAF-2010 cross section data library. The file is in the ENDF-6 MF = 33 format, and contains uncertainty data in a two-group format for threshold reactions from the threshold to 20 MeV and from 20 to 60 MeV. A four group format is adopted for the non-threshold reactions: from  $10^{-5}$  eV to  $E_V$  (the end of the  $1/v$  region),  $E_V$  to  $E_H$  (the end of the resonance region),  $E_H$  to 20 MeV and 20 to 60 MeV. The uncertainty values adopted correspond to the error factor  $f$ :

$$f = 1 + \Delta$$

where  $\Delta$  is the relative error ( $\Delta^2$  is actually stored in the file) in the cross section  $\sigma$ . In this case the best estimate of the cross section uncertainty is:

$$\sigma/f < \sigma < \sigma f$$

The emphasis for EAF-2010 uncertainties has been to include, as much as is possible, the experimental information, information from TALYS model calculations and SACS analysis. For threshold reactions, experimental variance information at 14 MeV is available for 1,085 reactions. These uncertainties have been estimated from the data scatter around the library excitation curve in EXFOR plots or from the now growing data base of experimental validation [125-

164]. This 14 MeV experimental variance is used for the energy range of the excitation function up to 20 MeV, and because no information on uncertainties at other energies has been used, an uncertainty value of  $\Delta\sigma = 3\Delta\sigma_{exp}$  has been adopted. This represents a 99.9% confidence limit. For non-threshold reactions, thermal cross section and resonance integral information are used for the first two energy ranges. For the smooth statistical range, the uncertainty factor is usually estimated from the scatter of EXFOR data around the evaluated curve and, for the high-energy range, the uncertainty value from the third range is generally assumed.

In the numerous cases where no experimental values are available, the uncertainty is extracted from systematics, results of graphical information or estimates. Depending on the reaction type, data origin and energy range the uncertainty value may vary from less than a few percent to a factor of five in exceptional cases. The bulk of the uncertainties however, range from a few percent to a factor of two.

Another important aspect of the uncertainty treatment occurs when the cross section is split. In general for uncertainties of cross sections to ground and isomeric states an uncertainty factor of the branching ration ( $f_b$ ) of 1.3 has been adopted when the branching is derived from systematics.

By definition  $\sigma_m = b\sigma$  and  $\sigma_g = (1-b)\sigma$ . Thus the uncertainty in  $\sigma_m$  is given by:

$$\left(\frac{\Delta\sigma_m}{\sigma_m}\right)^2 = \left(\frac{\Delta b}{b}\right)^2 + \left(\frac{\Delta\sigma}{\sigma}\right)^2$$

and  $\Delta\sigma/\sigma = f - 1$  and  $\Delta b/b = f_b - 1$ . Thus:

$$f_m = f_g = 1 + \sqrt{f_b^2 + f^2 - 2(f + f_b - 1)} \quad (1)$$

If experimental values of partial cross sections are known their uncertainties are adopted, although this is rare. Such a method of uncertainty propagation to the partial cross sections is certainly pessimistic although if no experimental data exist for the branching ratio their generation using systematics is not without error and an uncertainty of 30% is considered as sound pending further investigation.

An example of the EAF uncertainty file format is given in Appendix 1. Further details of the uncertainties and their use in FISPACT are presented in reference 1.

As the starter file for extensions and improvements for EAF-2010 the EAF-2007 uncertainty file [3] has been chosen. In order to make the  $\Delta\sigma$  assignment in a consistent manner, new rules for their determination have been put into place and are discussed here. All previous assignments have been reviewed and if needed changed following these new rules.

### Uncertainty assignments for total threshold cross-sections

In cases where differential experimental data exist, the relative uncertainty error is related to the position of these data and the energy range they cover on the excitation curve. In general a bell shaped excitation function is assumed and the following rules have been adopted. The position of energy ranges on the excitation curve is categorized in figure 81.

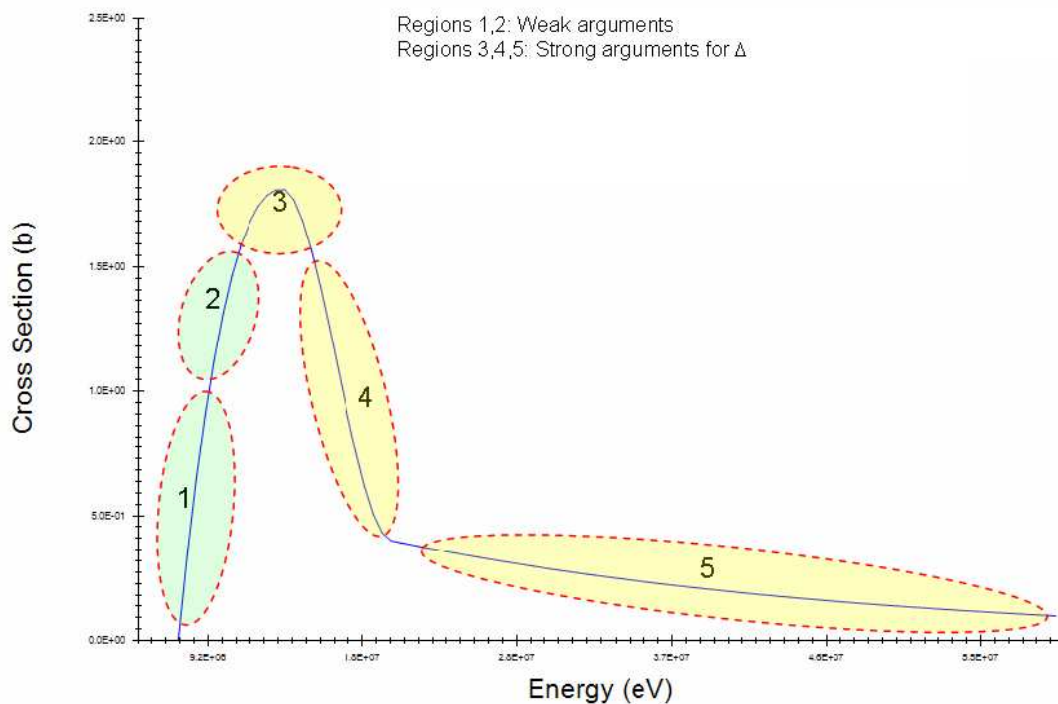

Figure 81. Position of experimental data on an excitation curve.

Regions 1 and 2 are located on the rising slope of the excitation curve (often close to the reaction threshold) and the experimental data represent a weak argument for the validation of the whole curve, especially as the data do not directly address the  $\sigma_{\max}$  value. However, if the predictability of the whole excitation curve (its shape) is good, these data offer reasonable support for the uncertainty estimate of the whole excitation curve.

Regions 3 and consequently 4 and 5 are regions where experimental information can be used both for validation and assignment of the

uncertainty errors. Region 3 covers the  $\sigma_{\max}$  and verifies also the position of  $E_{\max}$ . Regions 4, 5 cover the descending slope of the excitation curve towards the higher energies, where the competing reactions start to play an important role (often close or above 20 MeV) and where any experimental information are very valuable. Unfortunately, in practice such experimental data are very scarce.

Based on experience from visual analysis of library cross sections against EXFOR, the following rules for relative uncertainty errors have been proposed for different energy regions. They represent the lower limit of the estimated uncertainty.

Table 12. Rules for the determination of  $\Delta$  for different regions

Region = 1	$\Delta = 0.3$
Region = 2	$\Delta = 0.2$
Regions = 1 + 2	$\Delta = 0.2$
Region = 3	$\Delta = 0.1$
Region = 3 + others	$\Delta = 0.1$
Region = 4	$\Delta = 0.2$
Region = 5	$\Delta = 0.3$

In cases where the uncertainty is estimated by the author of an evaluation, it is used. However, such information is typically made more challenging by the evaluation processes, relying also on calculation and usually carrying systematic error.

The following remarks can be made on the predictability of the excitation curves adopted in EAF-2010:

For neutron emission channels: (n,n'), (n,xn), (n,n'p), (n,n'α) reaction cross section curve, the shape of the calculated cross sections is in good agreement with the trend derived from experimental data and is considered to be well identified.

For charge particle emission channels: (n,p), (n,d), (n,α) cross section curves are also believed to have a well described shape. However, two caveats exist that require special treatment. They are the width dependence of (n,p) reaction in the transitional range with asymmetries  $0.08 < s < 0.12$  [173], in which range a broadening of the excitation curve with energy takes place. The second exception is for (n,α) reaction, where  $\sigma_{\max}$  has been checked with SACS analysis. It was noted that, for targets with  $A > 100$ , the calculated value is too large. For the remaining reactions, (n,t) data are now in good agreement. A problematic situation still exists for (n,h) and (n,2p) reactions. Their experimental data (especially activation measurements) are often overestimated due to the interference of competing reactions from elemental or isotopic impurities. The

comparison between experimental data and calculated excitation curves is usually meaningless. For targets with important (n,n'p) or (n,d) reactions, an additional test can be applied using the visual analysis of (n,n'p) + (n,d) data against many available activation experiments.

Non-threshold (n,p) and (n, $\alpha$ ) reactions, for which a Low Energy Approximation (LEA) below the effective threshold  $E_{\text{eff}}$  has been applied, are treated as non-threshold reaction class with four energy groups. Where a LEA approximation could not be used, due to the small calculated cross section at 1 keV (TALYS calculation with  $\sigma < 10^{-19}$  b), they remain in the threshold section with two energy groups, usually with energies  $10^{-5}$  eV  $- E_{\text{eff}}$  and  $E_{\text{eff}} - 60$  MeV and with an uncertainty below  $E_{\text{H}}$  with an error factor set by default to 10.

In cases where no experimental information is available, the uncertainty is, as in the previous EAF-2007 uncertainty file, extracted from systematics, results of graphical information or from estimates. The extensive experience, capitalised from graphical comparisons, best estimates based on analyses of the scatter of calculated data from different libraries with different codes, has been added to estimates of those error factors. Furthermore, experience from previous exercises and performance tests performed on several TALYS calculations and validation exercises have also been accounted for. In this library the results of SACS analysis [173] have also been embedded. The results have shown that the error factors adopted in EAF-2007 were, for some reactions unnecessarily conservative and new more realistic values are proposed and listed in Table 13 (and earlier in Table 1) for important major reactions.

Table 13. Error factors derived from  $\sigma_{14.5}$  systematic or estimates based on EAF validations

Reaction	Systematic	Error factor (f)
(n,n')	Vonach	2.0
(n,2n)	Badikov	1.4
(n,3n)	Estimate	3.0 $\rightarrow$ 1.8 <sup>a</sup>
(n,4n)	Estimate	3.0 $\rightarrow$ 2.0 <sup>a</sup>
(n,n' $\alpha$ )	Estimate	3.0 $\rightarrow$ 2.0 <sup>a</sup>
(n,d)	Forrest	3.0 $\rightarrow$ 2.0 <sup>b</sup>
(n,n'p)	Kopecky	2.0
(n,t)+(n,n'd)	Forrest	1.6
(n,n't)	Estimate	5.0 $\rightarrow$ 3.0 <sup>a</sup>
(n,n'h)	Estimate	5.0 $\rightarrow$ 3.0 <sup>a</sup>
(n,f)	Estimate	2.0
(n, $\gamma$ )	Kopecky	2.0 $\rightarrow$ 1.5 <sup>c</sup>
(n,p)	Forrest	1.5
(n,h)	Lishan	1.9

Reaction	Systematic	Error factor (f)
(n, $\alpha$ )	Madjdeddin	1.6
(n,2p)	Estimate	3.0
Other reactions	Estimate	3.0

→ Indicates differences between EAF-2007 and EAF-2010

<sup>a</sup> Neutron emission channels have been shown to be in good agreement with the experimental data and therefore more accurate estimates are proposed for (n,xn) reactions.

<sup>b</sup> For (n,d) reactions with targets where asymmetry,  $s < 0.1$ , the results are in reasonable agreement with experiments with a well defined systematic formula. For heavier targets ( $s > 0.1$ ) the accuracy is less good. However, the (n,n'p) reaction becomes dominant and (n,n'p)+(n,d) can be used as an additional check.

<sup>c</sup> This is extensively discussed in [172].

### **Uncertainty assignments for partial threshold cross-sections**

For a consistent treatment of uncertainties for split reactions with experimental values of partial cross sections, the following rules have been adopted, as described in Table 14. Since not all of these uncertainties are often experimentally known, we have adopted the rule to apply them only if  $\Delta\sigma_g$  and/or  $\Delta\sigma_m$  are not available.

Table 14. Rules for targets with cross sections to isomeric states

$\sigma_t$	$\sigma_g$	$\sigma_m$	Uncertainty assignment
$\Delta(\text{exp})$	-	-	$\Delta_g$ and $\Delta_m$ calculated from eq. (1)
$\Delta(\text{exp})$	-	-	if either $\sigma_g$ or $\sigma_m$ are close to $\sigma_t$ $\Rightarrow \Delta(g,m) = \Delta(\text{exp})$
$\Delta(\text{exp})$	-	$\Delta(\text{exp})$	Larger of $\Delta(\text{exp})$ is adopted
$\Delta(\text{exp})$	$\Delta(\text{exp})$	-	Larger of $\Delta(\text{exp})$ is adopted
-	-	$\Delta(\text{exp})$	$\Delta_t = \Delta(\text{sys})$
-	$\Delta(\text{exp})$	-	$\Delta_g$ or $\Delta_m$ calculated from eq. (1)

### **Uncertainty assignments for total cross-sections**

As the starter file for extensions and improvements of the EAF-2010 uncertainties, the EAF-2007 uncertainty file for non-threshold reactions has been chosen. In order to ensure assignment of error factors is carried out in a consistent manner, new rules have been developed and are discussed here. The new approach has been implemented to account for a more quantitative estimate of uncertainties for the  $1/v$  component and the resolved and unresolved resonance region below 100 keV (the upper energy limit of the resonance integral). This approach employs experimental values of

thermal cross sections and resonance integrals including the corresponding C/E values. All previous assignments have been reviewed and, if required, have been changed following these new rules. New data are listed in Appendix 2 and include all non-threshold reactions.

### (n, $\gamma$ ) reactions

1/ $\nu$  energy region – The error factor is estimated from the uncertainty of the experimental value of the thermal cross section, typically from the recommended experimental value. If no experimental data are available, the cross section estimate [34] is applied and the default value of  $f = 10$  is used. This large value acts as a warning for the crudeness of this approach.

For reactions with experimental thermal cross section  $\sigma_{\gamma}(\text{thermal})$  we define the error factor of the 1/ $\nu$  ( $10^{-5}$  eV -  $E_V$ ) region, based on  $\sigma_{\gamma}(\text{thermal})$  validation, as

$$f(E_V - E_H) - 1 = \text{SQRT}((1 - C/E(I_{\gamma}))^2 + \Delta\sigma_{\gamma}^2) \quad (2)$$

in which  $C/E(\gamma)$  represents the fit of the adopted EAF data with the thermal cross section values of  $\sigma_{\gamma}(\text{exp.})$  and its error  $\Delta\sigma_{\gamma}$ . A default value of 1.1 is used if the error factor  $f$  is below 1.1. If the experimental thermal cross section is given without an error, then the error factor is set to  $f = 1.5$  (50% uncertainty). The agreement of the resonance integral data with experimental data is shown in Fig. 82 and demonstrates a good agreement.

Figure 82. C/E of the thermal cross section for (n, $\gamma$ ), (n,f), (n,p) and (n, $\alpha$ ) reactions.

### Resolved resonance region RRR ( $E_V - E_H$ )

The  $E_V$  or  $E_L$  in ENDF-6 and  $E_H$  values are either taken from the data source or estimated visually from the adopted cross section curve. In cases of a PENDF file (generated from resonance parameters) is available, a default value of  $f = 1.5$  is adopted. This value can become smaller or larger, depending on the resonance integral  $C/E$  value. The agreement of the resonance integral data with experimental data is shown in Fig. 83 and demonstrates again a good agreement. The reactions with  $C/E$  values with large deviations from unity are discussed in Appendix 3.

Figure 83.  $C/E$  of the resonance integral for  $(n,\gamma)$ ,  $(n,f)$ ,  $(n,p)$  and  $(n,\alpha)$  reactions

The procedure used to treat the experimental resonance integrals  $I_\gamma$  is as follows: assuming that the main contribution to the resonance integral comes from the resolved resonance region, it is appropriate to use the  $\Delta I_\gamma$  and  $|1-C/E(I_\gamma)|$  values as a combined source of uncertainty which can be included as an error factor. The energy limits of the resonance integral is between 0.5 eV and 100 keV and the following rules have been adopted with  $E_H(\text{exp})$  as the upper energy point of the resolved resonance region:

For all reactions with experimental  $I_\gamma$  data the values of  $E_V = 0.5$  eV and of  $E_H = 100$  keV adopted, even if the  $E_H(\text{exp})$  value is  $< 100$  keV. If  $E_H(\text{exp})$  is larger than 100 keV then this value is used. If the whole region ( $E_V - E_H$ ) is above 100 keV, then  $E_V = 0.5$  eV and  $E_H = 100$  keV are used. This often occurs for very light nuclei and  $I_\gamma$  for these cases, information on the extended tail of the  $1/v$  component is given.

For reactions with the Single Resonance Approximation (SRA), the assigned resonance is included in the  $(E_V - E_H)$  region as a single resonance with  $f = 2$  for the region.

It has been found that the  $C/E$  ratio of  $I_\gamma$  is an important validation quantity from low energies up to 100 keV.

We define the error factor of the resolved resonance  $(E_V - E_H)$  region, based on  $I_\gamma$  validation, as:

$$f(E_V - E_H) - 1 = \text{SQRT} \left( (1 - C/E(I_\gamma))^2 + \Delta I_\gamma^2 \right) \quad (3)$$

in which  $C/E(I_\gamma)$  represents the fit of the adopted EAF data with the resonance integral values of  $I_\gamma(\text{exp})$  and  $\Delta I_\gamma$ . A default uncertainty value of 1.1 is used if the experimental values are below 1.1.

If the cross section in the resonance region is based on statistical calculations only, extends down to 1 keV and the  $C/E(I_\gamma)$  value exists, this value is used. In cases where no experimental information is available for this energy region,  $E_V$  is as used and set equal to  $E_H$  and  $f(E_V - E_H) = 2.0$ .

### The statistical region ( $E_H - 20$ MeV)

This region is composed from the statistical Hauser-Feshbach region and the pre-equilibrium component, the latter typically starting at about 8 MeV. The statistical region is usually well validated up to 10 MeV. The error factor is estimated from the visual agreement with experimental data. In cases of good agreement  $f = 1.5$  is used as a default value to cover a rather steep decrease of this cross section down to several mb typical of the pre-equilibrium component. Only in cases when an excellent agreement exist lower values (usually 1.3) are used. The single 30 keV data point is counted as a sufficient experimental support, based on the results in [172]. If no experimental data exist then the  $\sigma(30 \text{ keV})$  cross-section systematic is consulted and used for a judgment of the fit and, in cases of reasonable agreement, the default values between  $f = 1.8$  and 2.0 are used. There are strong arguments from the EAF and TALYS data validations that the 30 keV experimental and systematic cross sections can be used to estimate the error factor of the statistical component [172] and Figs. 84 and 85.

Figure 84. C/E of 30 keV (n,γ) cross section

Figure 85. C/S of 30 keV (n,γ) cross section data in EAF-2007

Ratios far below unity are usually from reactions where the 30 keV energy point lies within the resolved resonance region. The pre-equilibrium process dominates the region above 10 MeV and  $\sigma_{14.5}$  is an important test point. This value is validated either against the experimental data or the  $\sigma_{14.5}$  cross section systematic, which is rather accurate with values around 1 mb. The C/E and C/S histograms, shown in Figures 86 and 87, again demonstrate the suitability of this approach to estimate the uncertainty in this region. The statistical contribution, however, dominates the group cross-section in this region and therefore is used as main information for the whole region ( $f = 1.5$  or better, it was  $f = 2.0$  in EAF-2007). For a detailed description of 30 keV and 14.5 MeV data and their analysis see [172].

Figure 86. C/S of 14.5 MeV (n,γ) cross section data in EAF-2007.

Figure 87. C/E of 14.5 MeV (n,γ) cross section data in EAF-2007

For the high-energy region, 20 to 60 MeV, practically no experimental information are available and the error factor has usually been kept the same as for the previous region below 20 MeV region.

### ***Uncertainty assignments for non-threshold cross-sections***

#### **(n,f) reaction**

For the  $1/v$  energy region the same rules as for (n,γ) data are also applied here. The only difference is that the  $\sigma_{th}$  systematic of Behrens is considered as more accurate and therefore the error factor for

reactions without experimental thermal cross section data is set to  $f = 5.0$ .

For the resolved resonance region ( $E_V - E_H$ ) the same rules as for (n, $\gamma$ ) data are also applied. The conservative  $f$  value ( $f = 2$ ) is recommended when for the data source is estimated.

For the statistical region ( $E_H - 20$  MeV) and contrary to the (n, $\gamma$ ) reaction this region is a transition from the resonance region, decreasing via the unresolved resonance component to the multi-chanced fission region. These two regions are connected with a rapid cross-section increase from about 100 keV up to 1 MeV (fission threshold), where the n-chance fission starts. The region up to 25 MeV includes the first-, second-, third- and fourth-chance fission and is often supported by a large number of experimental data with reasonably predictable trends. The error factor is estimated from the visual agreement with experimental data while for reactions with no experimental data  $f = 2.0$  has been adopted.

For the high energy region, 20 to 60 MeV only a very limited set of experimental information are available and the error factor is set by default to  $f = 2.0$ , in order to cover the uncertainty of adopted calculations.

All these rules are summarized in Tables 15 and 16 for (n, $\gamma$ ) and (n,f) reactions.

Table 15. Rules for error factors for (n, $\gamma$ ) and (n,f) for regions with experimental data.

Reaction	Region	Error factor (f)
(n, $\gamma$ )	1/v	derived from $\Delta\sigma$ (0.0253 eV) in Eq. (2)
(n, $\gamma$ )	$E_V - E_H$	= 1.5 if only resolved resonance data are available and no resonance integrals $> 1.1$ based on $\Delta I_r$ taken from Eq. (3)
(n, $\gamma$ )	$E_V - E_H$	$< 1.5$ estimated from $> E_H$ average EXFOR data and/or from $\sigma(\text{sys})$ at 14.5 MeV
(n, $\gamma$ )	$E_H - 20$ MeV	= $f(E_H - 20 \text{ MeV})$
(n, $\gamma$ )	20 – 60 MeV	= $f(E_H - 20 \text{ MeV})$
(n,f)	1/v	derived from $\Delta\sigma$ (0.0253 eV) in Eq. (2)
(n,f)	$E_V - E_H$	1.5 if experimental resolved resonance data available
(n,f)	$E_H - 20$ MeV	$> 1.5$ dependent on the agreement with EXFOR data
(n,f)	20 – 60 MeV	= $f(E_H - 20 \text{ MeV})$

Table 16. Rules for error factors for (n, $\gamma$ ) and (n,f) for regions with no experimental data.

Reaction	Region	Error factor (f)
(n, $\gamma$ )	$1/v$ <sup>a</sup>	10.0
(n, $\gamma$ )	$E_V - E_H$	2.0
(n, $\gamma$ )	$E_H - 20$ MeV	>2.0
(n, $\gamma$ )	20 – 60 MeV	>2.0
(n,f)	$1/v$ <sup>b</sup>	5.0
(n,f)	$E_V - E_H$	3.0
(n,f)	$E_H - 20$ MeV	2.0
(n,f)	20 – 60 MeV	2.0

<sup>a</sup> Based on  $\sigma(\text{th}) = f(aU)$  crude systematic from [34]

<sup>b</sup> Based on systematic of Behrens from [52].

### (n,p) and (n, $\alpha$ ) reactions

Two groups of data are included in this section. Firstly, reactions with experimentally determined resonance parameters for p or  $\alpha$  exit channels and secondly reactions treated with Low Energy Approximation (LEA), where the resolved resonance region is approximated by the data from (n, $\gamma$ ) reaction, assuming a constant ratio of cross sections  $\sigma(\text{n,p})/\sigma(\text{n},\gamma)$  or  $\sigma(\text{n},\alpha)/\sigma(\text{n},\gamma)$  at low incident energies in the keV region.

The LEA component is generated from the  $1/v$  and resolved resonance regions taken from the corresponding (n, $\gamma$ ) reaction and normalized to the thermal cross section reaction value of the (n,p) or (n, $\alpha$ ) reaction. These thermal values are either taken from experiments or if no experiment are available, the TALYS calculated ratio  $\sigma(\text{n,p})/\sigma(\text{n},\gamma)$  or  $\sigma(\text{n},\alpha)/\sigma(\text{n},\gamma)$  at 1 keV is used.

Table 17. Rules for error factors for (n,p) and (n, $\alpha$ ) regions with LEA data.

RN of $1/v$ to $\sigma(\text{th.})$	Error factor (f) $1/v$	Error factor (f) $(E_V - E_H)$
$\sigma(\text{n,p})$ or $\sigma(\text{n},\alpha)$ exp.	$\Delta\sigma$ (0.0253eV) used	2.0
$\sigma(\text{n},\gamma)$ exp.	2.0	2.0
$\sigma(\text{n},\gamma)$ estimated	10.0	10.0

Secondly, the (n,p) and (n, $\alpha$ ) reactions with a  $1/v$  component directly coupled to a statistical calculation, and having no resonance regions; are treated as model derived channel and associated with only two-group uncertainty data set.

---

## ***Uncertainty assignments for branched cross-sections***

The same rules as for the threshold branched reactions are also applied to the non-threshold branched channels.

## **EAF data formats**

### ***Point-wise data formats***

The format of the EAF-2010 file is essentially that of the MF = 3 file of ENDF-5 format with the following deviations (the resulting format is usually referred to as the EAF format):

- Two comment lines have been added at an earlier stage, stating the origin of data, the SAFEPAQ-II modifications and the Quality score.
- The material number MAT consists of Z and the two last digits of A. To describe isomeric targets A has been increased by 50 or 70 (m or n, respectively). Consequently, the order of the cross sections (according to increasing MAT numbers) is not always in accordance with increasing Z and A. This applies only to the point-wise format data, not to the multi-group constant library, for which another MAT number with more digits is used.
- The identifiers LIS and LFS are used to indicate the (isomeric) states of the target and final nucleus, respectively. Here we have adopted the convention that LFS = 99 means total production cross section; LFS = 0, 1, or 2 means production of ground state, first and second isomeric state, respectively.
- The reaction nomenclature is as defined by ENDF, except that reaction numbers leading to isomeric states have been increased by 300 or 600 (for m and n, respectively). The cross sections for one material number are ordered according to increasing MT numbers, except that cross sections leading to isomeric states follow immediately after the cross section leading to the ground state.

The composition of the comment lines has been fully described in an earlier section. An example of the EAF point-wise file format is given in Appendix 2.

### ***Group-wise data formats***

SAFEPAQ-II calculates the multi-group file using a procedure which is fully described in reference 2. The format of the multi-group library, GXS\_EAF, is the LIBOUT format of the code FOUR ACES (ENEA Bologna), again with two additional comment lines

(modification data and Quality score are shown on the first, the second is blank) for each reaction. For reaction numbers the ENDF-reaction number MT multiplied by 10 has been adopted, with the convention that for the excitation of each isomeric state the reaction number is increased by one. The material numbers of EAF\_GXS consist of Z, A and an identifier to indicate ground or isomeric target ( $\text{MAT} = Z \times 10000 + A \times 10 + \text{LIS}$ ). The order of the cross sections on the EAF\_GXS file is in accordance with increasing Z, A, LIS, LFS and MT.

The multi-group file is produced in one of seven group-structures: that of GAM-2 (100 groups), VITAMIN-J (175 groups), WIMS (69 groups), XMAS (172 groups), VITAMIN-J+ (211 groups), TRIPOLI (315 groups) and TRIPOLI+ (351 groups) with appropriate flux-weighting spectra. However, if required the group structure could be changed into any other energy group structure or weighting function with a small amount of effort.

The accuracy of a set of multi-group constants is determined by the group structure and the weight function. This is particularly true when either the group structure is coarse (e.g. VITAMIN-J in the thermal range) or when the flux varies strongly between different regions of the device. Historically all of the weighting functions included a fission spectrum but that is not appropriate when the device is a fusion plant. Similarly having a fusion peak in the weight function used for a fission plant is not correct. Three distinct weight functions have been used to process the group-wise files. They are denoted as:

- FLA or FLT: a flat or constant weight function (not shown).
- FIS: this weight function combines a thermal Maxwellian at low energies, a  $1/E$  function at intermediate energies, and a fission spectrum ( $T = 1.3539$  MeV) with a fast dropping tail at higher energies shown in 87.
- FUS: this weight function combines a thermal Maxwellian at low energies, a  $1/E$  function at intermediate energies, and a velocity exponential fusion peak spectrum with a peak at 14.07 MeV shown in Figure 88.

An example of the EAF group-wise file format is given in Appendix 3.

Figure 88. EAF-2010 micro-flux weighting function for fusion.

## Conclusions

The neutron-induced cross section data included in comprehensive activation files such as EAF-2010 come from sources having varying degrees of quality. The processing code SAFEPAQ-II enables all the necessary modifications to be performed in a well defined and quality assured manner. This leads to the creation of an activation file that can claim a much higher degree of quality than the original sources. The validation of the processed data, in various energy ranges, allows the correctness of the data treatments to be certified at the processing stage.

However, it is important to note that although the file is probably as complete as required for magnetic fusion applications, the experimental database that allows internal validation by C/E analysis is far from complete and contains many deficiencies. Although systematic comparisons can be made at high energies, the derived uncertainty margins are higher and rely more on estimation than on an experimental comparison. This introduces higher calculational uncertainties and so forces wider safety margins for applications that rely on 14 MeV data. A greater range of experimental measurements is therefore urgently required.

In EAF-2010 results of a wide range of integral experiments have been used to adjust data. Validation of activation code predictions, and thereby of cross section and decay data, has been performed by means of direct comparison with measurements of various materials under fusion-relevant neutron spectra. Integral experiments are a rich source of information with which a wide range of validation and comparison exercises can be made in the activation data field. The broad trends of the time dependent values of the calculated-to-experimental ratios represent the best estimates of the uncertainties that should be applied to predictions made with activation codes.

## **Acknowledgements**

The development of EAF and the production of this documentation have been supported by United Kingdom Engineering and Sciences Research Council and the European Communities under the contract of Association between EURATOM and CCFE, and were carried out partly within the framework of the F4E Agreement. The views and opinions expressed herein do not necessarily reflect those of the European Commission.

Earlier EAF development at NRG Petten is recognised, and the authors would like to thank D Nierop for his many contributions. The authors acknowledge the support and dedication of many colleagues in the nuclear data community in the EU, RF, Japan and the USA without whom such work would have been impossible, in particular: P. Bém, A Filatenkov, M Herman, Y Ikeda, A Ignatjuk, A Mengoni, F Maekawa, W Mannhart, U von Möllendorf, A Pashchenko, M Pillon, K Shibata, K Seidel, S Tagessen, H Vonach, H Weigmann, WB Wilson and K Zolotarjev.

## **Disclaimer**

Neither the authors nor CCFE accept responsibility for consequences arising from any errors either in the present documentation or in the EAF libraries.

## **Contact person**

Feedback on the use of EAF is welcomed. Please contact J.-Ch. Sublet with comments.

## Appendix 4: Index of EAF-2010 reactions

A listing of all 66,256 reactions in the EAF-2010 cross section library is given in the list below. Each reaction is shown with the initial (IS) and final (FS) isomeric states, the origin of the data (see Table 4), the Quality score (see Table 12), the types of modifications made (see reference 2) and the number of data points in the point-wise library. At the start of each reaction the symbol '>' indicates that the data have changed between EAF-2007 and EAF-2010 while '+' indicates that the reaction is new in EAF-2010. Note that two columns per page are presented, read each page from the bottom of column 1 to the start of column 2.

## Appendix 5: Index of EAF-2010 targets

A listing of all targets in the EAF-2010 cross section library is given in the list below. Stable targets are indicated, half-lives are listed for radioactive targets and ENDF-6 MAT numbers are shown.

Nuclide	ZAIID	Half-life	MAT
H-1	1001	stable	125
H-2	1002	stable	128
H-3	1003	1.23E+01y	131
